## Background

Mounting evidence suggests that neuronal voltage-gated  $Ca_V 1.2$  and  $Ca_V 1.3$  L-type calcium channels (LTCCs) can modulate mood and anxiety behaviors. In Cav1.2 dihydropyridine (DHP)-insensitive mice (Ca<sub>v</sub>1.2DHP<sup>-/-</sup> mice), systemic application of the DHP channel activator BAYK 8644 induced pro-depression-like behavior providing evidence for a possible role of Ca<sub>v</sub>1.3 channels in mood behavior. We therefore explored the role of Ca<sub>v</sub>1.3 LTCCs in depression- and anxiety-like behaviors using Ca<sub>v</sub>1.3deficient mice (Ca<sub>v</sub>1.3<sup>-/-</sup>). However, Ca<sub>v</sub>1.3<sup>-/-</sup> mice are congenitally deaf and it is so far unclear how deafness affects emotional behavior in mice. We therefore used another mouse model suffering from congenital deafness, claudin 14-deficient mice (Cldn14-/-) as a control to address this question. As Ca<sub>v</sub>1.3 channels are expressed in the retina we also investigated Ca<sub>v</sub>1.3<sup>-/-</sup> mice for possible disturbances in retinal morphology and visual function that could interfere with behavioral analysis.

#### **Methods**

Depression-like behavior was assessed using forced swim and tail suspension tests (FST and TST) whereas elevated plus maze (EPM) and stress-induced hyperthermia (SIH) were performed to test anxiety-like behavior. Morris water maze, electroretinography and immunofluorescence stainings were performed to evaluate the consequence on visual acuity and retinal morphology of  $Ca_v 1.3$  deletion in  $Ca_v 1.3$ -<sup>-</sup> mice.

#### Results

We showed that  $Ca_V 1.3^{-/-}$  mice displayed less immobility in the FST as well as in the TST, indicating an antidepressant-like phenotype. In the EPM,  $Ca_V 1.3^{-/-}$  mice entered the open arms more frequently and spent more time there indicating an anxiolytic-like phenotype which was, however not supported in the SIH test. By performing parallel experiments in Cldn14<sup>-/-</sup> mice, an influence of deafness on the antidepressant-like phenotype could be ruled out. On the other hand, a similar EPM behavior indicative of an anxiolytic phenotype was also found in the Cldn14<sup>-/-</sup> animals. Using electroretinography and visual behavioral tasks we demonstrated that in mice,  $Ca_V 1.3$  channels do not significantly contribute to visual function. However, distinct morphological changes were revealed in synaptic ribbons in the outer plexiform layer of  $Ca_V 1.3^{-/-}$  retinas by immunohistochemistry. Although these changes have no major effects on visual function, they indicate a possible role of this channel type in structural plasticity at the ribbon synapse.

## Conclusion

 $Ca_V 1.3$  LTCCs modulate depression-like behavior but are not essential for visual function. The findings raise the possibility that selective modulation of  $Ca_V 1.3$  channels could be a promising new therapeutic concept for the treatment of mood disorders.
