Introduction: Fluticasone furoate (FF)/vilanterol (VI) dry powder inhaler (DPI) is the only once-daily maintenance inhaled corticosteroid (ICS)/long-acting β_2 adrenergic agonist (LABA) combination for asthma. We aimed to compare the clinical effects of once-daily FF/VI and twice-daily budesonide (BUD)/formoterol (FM) DPI in patients with controlled stable asthma.

Methods: We performed a randomized crossover trial in which stable asthmatic patients controlled on ICS/LABA received 8 weeks of FF/VI (100/25 μg 1 puff once-daily) or BUD/FM (160/4.5 μg 2 puffs twice-daily) DPI treatment. After a 4–8-week washout period, patients received another crossover treatment for 8 weeks. We assessed pulmonary function, the 5-item version asthma control questionnaire (ACQ5), the asthma control test (ACT), and fractional exhaled nitric oxide (FeNO) at baseline and after 8 weeks of treatment (week 8). As the primary outcome was change in force expiratory volume in 1 s (FEV_1) between baseline and week 8, we evaluated the incidence of asthma exacerbation and adherence barrier questionnaire (Ask-12) at week 8.

Results: Twenty-three patients were initially enrolled in this study; however, one patient had to be excluded. The FF/VI DPI treatment group showed a similar magnitude of change in FEV_1 between baseline and week 8 as the BUD/FM DPI treatment group. In addition, there were no significant differences in pulmonary function tests, ACQ5 scores, ACT scores, and FeNO between baseline and week 8 in both groups. Although the incidence of exacerbation did not differ between groups, the Ask-12 score in the FF/VI DPI group was significantly lower than that in the BUD/FM DPI group.

Conclusions: The present study indicates that once-daily FF/VI DPI is not inferior to twice-daily BUD/FM DPI in clinical effect and more likely to improve inconvenience and forgetfulness in inhalation adherence barriers for stable asthma control therapy. Once-daily FF/VI DPI may be an effective alternative for asthma maintenance treatment.

Keywords: fluticasone furoate/vilanterol, budesonide/formoterol, stable asthma, randomized crossover trial, inhalation adherence barriers

Introduction

Fluticasone furoate (FF) is an inhaled corticosteroid (ICS) that confers both greater affinity for the glucocorticoid (GC) receptor and longer retention in respiratory tissues than does fluticasone propionate (FP). Once-daily FF has greater anti-inflammatory

activity and is more effective than are FP and budesonide (BUD).¹ Furthermore, inhaled FF showed longer absorption time from lung into the systemic circulation than inhaled FP.² In patients with asthma, some randomized clinical studies have demonstrated FF improved pulmonary function, rescue inhaler use, and symptom-free compared to placebo or FP.^{3–6} Vilanterol (VI) is a once-daily inhaled long-acting β_2 adrenergic agonist (LABA) shown to produce prolonged bronchodilation for at least 24 hrs. The fluticasone furoate/vilanterol (FF/VI) dry powder inhaler (DPI) combination device, Ellipta® (GlaxoSmithKline, UK), is an easy-to-use once-daily inhalation device. Most asthma patients made less errors using Ellipta than those using other devices.^{7,8} Inhaler errors in asthma management are associated with poor adherence and outcomes,⁹ and as such, the FF/VI Ellipta device may provide improved patient adherence and treatment outcomes. Previous clinical studies of FF/VI DPI delivered from a single inhaler, conducted in patients with asthma, have confirmed efficacy and safety of the treatment.^{10–15} These randomized control studies have compared the effects of FF/VI DPI combination versus placebo or fluticasone propionate/salmeterol (FP/SLM) DPI on acute exacerbations, pulmonary function, health-related quality of life, and adverse effects, in patients with chronic asthma. In addition, there have been some reports to compare FF/VI DPI therapy with other ICS/LABA combinations, such as budesonide/formoterol (BUD/FM) DPI, and assess patient adherence in asthma inhaler treatment recently.^{15,16} Therefore, we conducted this randomized crossover study to compare the clinical effects and inhalation adherence barriers of once-daily FF/VI DPI versus twice-daily BUD/FM DPI in patients with controlled stable asthma on ICS/LABA treatment. The primary outcome of this study was changes in force expiratory volume in 1 s (FEV₁). Secondary outcomes were to evaluate changes in other pulmonary function tests, the 5-item version asthma control questionnaire (ACQ5), the asthma control test (ACT), and fractional exhaled nitric oxide (FeNO) at baseline and after 8 weeks of treatment. In addition, the incidence of asthma exacerbation and adherence barrier questionnaire (Ask-12 survey) were assessed.

Materials and methods

Subjects

Patients aged 18 years or older, who were treated at Hamamatsu University School of Medicine between April 2014 and April 2015, were enrolled in this study. Patients

with asthma whose disease was classified as “controlled,” according to the Global Initiative for Asthma (GINA) criteria¹⁷ of asthma control, had undergone treatment of two actuations of BUD/FM DPI combinations (160/4.5 μg) 2 puffs twice-daily for at least 3 months. All the patients were treated with GINA step 4 therapy at the registration. The exclusion criteria were as follows: (1) treatment with oral or intravenous corticosteroids in the previous 4 weeks, (2) current smoker or having a smoking history of >10 pack-years, or (3) other pulmonary diseases, including chronic obstructive pulmonary disease (COPD), lung cancer, or pulmonary fibrosis. Asthma exacerbation was defined as any of the following events due to asthma symptoms: unexpected or emergency visit to the hospital, hospitalization, and systemic corticosteroid administration for more than 3 days.

Study design

This was a prospective, randomized, open-label, two-period crossover study of the FF/VI DPI versus BUD/FM DPI therapies, conducted in accordance with the Declaration of Helsinki (Figure 1). The patients who met the entry criteria completed over 2-week run-in period for evaluation of pulmonary function baseline and asthma status. After run-in period, the patients who met eligibility criteria were randomly assigned (1:1) to each of the two groups. The central randomization schedule was generated by using a computer program in our university. They received 8 weeks of FF/VI DPI treatment (100/25 μg) 1 puff once-daily or BUD/FM DPI treatment (160/4.5 μg) 2 puffs twice-daily. After a 4–8-week washout period, these patients received another crossover treatment for 8 weeks. During this study, the additional inhaled ICS other than FF and BUD, LABAs other than VI and FM, long-acting muscarinic antagonist (LAMA), theophylline, mucolytic agents, leukotriene receptor antagonist (LTRA) were withdrawn. A rescue inhaled short-acting β_2 adrenergic agonist (SABA) was used on demand to control symptoms throughout the study. We assessed changes in FEV₁ as a primary outcome, other pulmonary function tests, ACQ5, ACT, and FeNO at baseline and after 8 weeks of treatment (week 8). The incidence of asthma exacerbation and adherence barrier questionnaire (Ask-12 survey) were also evaluated at week 8. The study protocol was approved by the institutional review board of Hamamatsu University School of Medicine (HUSM 14–146). All patients provided written informed consent. The trial was registered with the University Hospital Medical

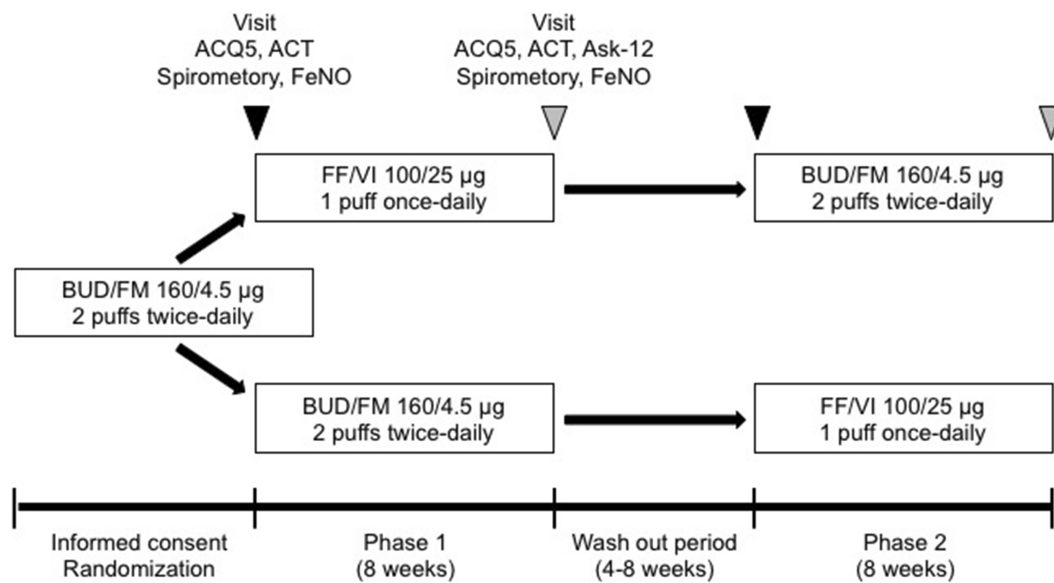

Figure 1 Study design. Stable asthmatic patients received 8 weeks of fluticasone furoate/vilanterol (FF/VI) dry powder inhaler (DPI) (100/25 µg 1 puff once-daily) or budesonide/formoterol (BUD/FM) DPI (160/4.5 µg 2 puffs twice-daily) treatment. After a 4–8-week washout period, patients received another crossover treatment for 8 weeks. We assessed pulmonary function, the 5-item version asthma control questionnaire (ACQ5), the asthma control test (ACT), and fractional exhaled nitric oxide (FeNO) at baseline and after 8 weeks of treatment (week 8). The incidence of asthma exacerbation and an adherence barrier questionnaire (Ask-12 survey) were evaluated at week 8.

Information Network (UMIN) Clinical Trial Registry (UMIN ID 000015609).

Measurements

Pulmonary function tests

Spirometry was performed at all visits using CHESTAC-8100 (CHEST M.I. Co., Ltd., Tokyo, Japan) according to the standards of the American Thoracic Society.¹⁸ The forced vital capacity (FVC), FEV₁, ratio of FEV₁/FVC, maximum mid-expiratory flow rate (MMF), maximum expiratory flow rate at 50% FVC (V₅₀), and 25% FVC (V₂₅) were evaluated.

ACQ5 and ACT scores

The ACQ5 consisted of five items assessing nocturnal waking, morning symptoms, activity limitation, shortness of breath, and wheeze during the previous 7 days, excluding frequency of short-acting β₂ agonist (SABA) use and FEV₁% predicted. Each item was scored on a scale of 0 to 6, where 0 represents good control and 6 represents poor control.¹⁹ The overall score of the ACQ5 was the mean of the five responses. The cut-off point for well controlled asthma was ≤0.75 whereas a value of ≥1.50 confirmed uncontrolled asthma.²⁰ A change of 0.5 in each score was considered a clinically meaningful difference, ie, minimum important difference.¹⁹ The ACT was a simple questionnaire, recommended by GINA.¹⁷ The ACT score

consisted of five questions assessing asthma symptoms (daytime and nocturnal), use of rescue medications, and the effect of asthma on daily functioning. The ACT scores for each of the five items were summed to yield a score ranging from 5 to 25 with a higher score indicating better asthma control.^{21,22}

Fractional exhaled nitric oxide (FeNo)

Fractional exhaled nitric oxide was measured using the commercially available analyzer NIOX MINO (Aerocrine AB, Solna, Sweden), according to recommendations from the American Thoracic Society/European Respiratory Society.²³

Ask-12 adherence barrier survey

The Ask-12 survey is a 12-item, self-administered questionnaire designed to assess behavior and barriers associated with medication adherence (Table S1).²⁴ The Ask-12 survey consisted of 12 items in three subscales, including inconvenient/forgetfulness, health beliefs, and behavior items, for adherence barriers assessment. Items 1 to 7, which assess barriers to treatment adherence, were rated with the following five response options: strongly agree, agree, neutral, disagree, and strongly disagree. Items 8 to 12 assessed adherence behavior. For all items, except items 4 to 7, higher scores suggested greater problems with adherence. Items 4 to 7 were reverse scored so

that their final recoded scores were in the same direction, with higher scores representing stronger barriers to adherence. The Ask-12 total score range was 12 to 60 points, with higher scores representing greater barriers to adherence. In this study, patients with good adherence were defined as 1 point (strongly disagree) or 2 points (disagree), while patients with poor adherence were done as 4 points (agree) or 5 points (strongly agree) on item 1, “I just forget to take my medicines some of the time.” at week 8. We assessed all outcomes in the patients with good adherence between FF/VI DPI and BUD/FM DPI groups.

Statistical analysis

The target sample size was 22 patients in each group, which provided 80% power at a two-sided α level of 5% to detect a difference of 90 mL or over in FEV₁, assuming a standard deviation (SD) of 40 mL in both groups, and the non-inferiority margin was 0.2 L. Data are shown as the mean \pm SD. The treatment difference of change in FEV₁ as a primary endpoint between FF/VI DPI and BUD/FM DPI groups was analyzed by Welch's *t*-test. We analyzed the incidence of asthma exacerbation, ACT scores, and Ask-12 scores and compared these between the FF/VI DPI and BUD/FM DPI groups with Pearson's chi-squared test or Wilcoxon rank sum test. We compared between the baseline and post-treatment values in each inhalation device by paired *T*-test, and assessed the difference between both treatment groups by multivariate analysis of variance (MANOVA). All statistical analyses were performed with JMP[®] 13.2.0 (SAS Institute Inc., Cary, NC, USA). A *p*-value of <0.05 was considered statistically significant.

Results

Patient characteristics

A total of 23 patients were initially enrolled in this study; however, one patient who dislocated her temporomandibular joint during the study had to be excluded. Patient characteristics are described in Table 1. Briefly, the mean age was 62.0 years and 63.6% of patients were female. The mean body mass index (BMI) was 23.9 kg/m². Fifteen patients had never smoked and seven were former smokers. The mean duration of treatment with BUD/FM DPI for asthma was 17.5 months. Eight patients had already been treated with LTRA. No patient received tiotropium or theophylline as a controller, while five

patients had undergone antihistamines therapy (Table 2). Three patients experienced asthma exacerbation during this study (Table 3). All of the asthma exacerbation cases were unexpected visit to the hospital and systemic corticosteroid administration for more than 3 days. The incidence of exacerbation was not significantly different between both groups (FF/VI 9.1% vs BUD/FM 4.6%; *p*=0.5498).

Changes in pulmonary function, asthma control, and fractional exhaled nitric oxide (FeNO)

There were no significant differences in pulmonary function parameters, ACQ5 scores, ACT scores, and FeNO between baseline and after week 8 of treatment in each treatment group (Table 4). In comparison between FF/VI DPI and BUD/FM DPI treatment groups, the FF/VI DPI treatment group showed a similar magnitude of change in FEV₁ between baseline and week 8 as the BUD/FM DPI treatment group (FF/VI 2.15±0.54 to 2.08±0.54 L vs BUD/FM 2.07±0.53 to 2.10±0.51 L; $p=0.203$). The treatment difference of change volume in FEV₁ in FF/VI DPI treatment was -53 mL (95% CI, 29 mL to -136 mL, $p=0.200$) within non-inferiority margin of BUD/FM DPI group. In addition, we evaluated changes in other pulmonary function parameters in the FF/VI DPI treatment group and noted that they were not different to those in the BUD/FM DPI treatment group. There were no significant changes in ACQ5 scores (FF/VI 0.29±0.41 to 0.39±0.54 vs BUD/FM 0.35±0.42 to 0.39±0.51; $p=0.4024$), ACT scores (FF/VI 23.8±1.83 to 23.5±1.96 vs BUD/FM 23.3±2.10 to 23.6±2.21; $p=0.2185$), and FeNO (FF/VI 26.1±19.5 to 24.3±19.6 ppb vs BUD/FM 23.5±17.4 to 25.7±17.7 ppb; $p=0.2530$) between both treatment groups.

Adherence assessment using the Ask-12 survey

We assessed behavior and barriers related to inhaler device adherence for asthma maintenance treatment using the Ask-12 survey (Table 5). The Ask-12 total score in the FF/VI DPI group was significantly lower than that in the BUD/FM DPI group (FF/VI 19.3±5.71 vs BUD/FM 24.1±8.60; $p=0.0366$). In subscale analysis, health beliefs and behavior scores were not significantly different between both groups; on the other hand, the inconvenience and forgetfulness score in the FF/VI DPI group was significantly lower than that in the BUD/FM DPI group (FF/VI 5.40±2.93 vs BUD/FM 7.05±2.69; $p=0.0425$). The results indicate that FF/VI DPI treatment had significantly less inconvenience and forgetfulness associated with the therapy as well as better adherence barriers compared to BUD/FM DPI treatment.

Discussion

This study showed that in patients with stable asthma controlled with ICS/LABA, the clinical effect of once-daily FF/VI DPI treatment was not inferior to that of

twice-daily BUD/FM DPI therapy. In addition, FF/VI DPI significantly reduced inconvenience and forgetfulness scores in Ask-12 survey and may improve inhaler device adherence barriers compared with BUD/FM DPI. Recent studies have reported that FF/VI DPI had better clinical efficacy in improving asthma symptoms, pulmonary function, and health-related quality of life, and in reducing asthma exacerbation compared to placebo or other optimized usual care.¹⁰⁻¹⁵ However, the patients analyzed in these studies had uncontrolled asthma. Additionally, there are few studies that assess inhaler device adherence barriers for maintenance treatment in controlled asthma patients. Consequently, we investigated the clinical effects and inhalation adherence barriers of once-daily FF/VI DPI compared with twice-daily BUD/FM DPI in patients with controlled stable asthma on ICS/LABA therapy in a randomized crossover study.

Fluticasone furoate/Vilanterol is an ICS/LABA combination therapy with inherent 24 hrs activity, currently used as a once-daily treatment device. Fluticasone furoate has been shown to have stronger affinity for the GC receptor and longer activation in respiratory cells compared with other GCs.¹ In particular, the drug was several times more potent than BUD in inhibiting inflammatory cytokine production in respiratory.¹ Furthermore, inhaled FF demonstrated prolonged absorption from lung into the systemic circulation compared to inhaled FP.² Actually, some clinical studies have reported that FF DPI improved peak expiratory flow, pre-dose evening FEV₁, and treatment effect on rescue/symptom-free compared to placebo or other ICS in patients with asthma.³⁻⁶ Additionally, Vilanterol is a once-daily inhaled LABA shown to induce prolonged bronchodilation for at least 24 hrs. VI has a stronger affinity for β_2 adrenergic receptor than FM, and is faster and longer acting than SLM.²⁵ Accordingly, FF/VI DPI (100/25 μg) 1 puff once-daily has been expected to have a clinical effect comparable to BUD/FM DPI (160/4.5 μg) 2 puffs twice-daily for inhaled asthma treatment. In this study, we found that there were no differences in incidence of asthma exacerbation, pulmonary function parameters, and symptom scores between FF/VI DPI (100/25 μg) 1 puff once-daily and BUD/FM DPI (160/4.5 μg) 2 puffs twice-daily. We suggest FF/VI DPI once-daily therapy as an alternative control in patients with stable asthma controlled on BUD/FM DPI twice-daily.

The effectiveness of inhaled therapy for asthma is strongly influenced by the adherence and inhaler technique of these inhalations, as poor inhaler adherence and

technique error have led to poor asthma control.^{9,26,27} Recently, comparative clinical studies have reported on errors in handling and wrong technique use for various inhaler devices.⁷⁻⁹ On the other hand, patient adherence has been recently assessed using some different subjective scales, such as the Morisky medication adherence scale (MMAS),²⁸ the medication adherence rating scale (MARS),²⁹ and the “Adherence starts with knowledge 20” (Ask-20) questionnaire.^{30,31} Clinical studies using the Ask-20 questionnaire have recently reported correlations between adherence and adherence barriers to inhaled treatment in patients with asthma.^{32,33} The Ask-20 total score discriminated between those patients with good and poor medication adherence as patients with poor adherence to inhaled medicines had significantly higher total Ask-20 scores.^{32,33} However, the questionnaire is comprised of twenty items and a specific part of the questionnaire does not address inhalation technique or education.³³ Therefore, the Ask-20 questionnaire as adherence barriers assessment tool is not widely used in the inhaled medication clinical field.³⁰ In this study, we performed the Ask-12 survey, which is modified from the Ask-20 survey, and can be used in daily medical practice.^{24,34} Previous studies reported that the Ask-12 total score correlated with pharmacy-refill rates^{24,34} and that the optimal cut-off value of the total score was 23 points to discriminate poor adherence with inhalation treatment.³⁴ We found that the Ask-12 total score associated with the once-daily FF/VI DPI device was significantly lower than that of the twice-daily BUD/FM DPI, and that the asthma patients who used the once-daily inhaler had a reduced adherence barrier related to inconvenience and forgetfulness than those using the twice-daily device. An additional reason for this improvement is likely that the FF/VI DPI device (Ellipta) was easy to use, had fewer steps, shorter instructions, and a more intuitive design.⁷ Recent studies have shown that the Ellipta device caused less errors in inhaler treatment compared to other inhaler devices,⁷ and asthma

patients were able to learn the correct use of the device after being instructed only three times.⁸ In this assessment of the Ask-12 survey, we showed that the inconvenience and forgetfulness scores of the Ellipta, a simple and once-daily device with low error rates, were significantly decreased when compared to that of another twice-daily device.

The present study had some limitations. The study involved open-label administration, had a short duration of treatment, and had a relatively small sample size. In particular, open-label prospective study has potential biases and could influence results in some clinical endpoints. Furthermore, we used the subjective measurement of self-reported adherence barriers without the objective measures of adherence such as dose counter or monitoring devices in this study. We think that a much larger and longer study would be required to confirm comparable clinical effectiveness including asthma exacerbation and improving adherence barriers in different inhaled devices for controlled asthma maintenance therapy. However, this study is important in terms of being one of the randomized crossover trials to compare the pulmonary functions and adherence barriers between once-daily and twice-daily inhaled therapies for stable asthma.

Conclusion

This study indicated that the clinical effect of once-daily FF/VI DPI was not inferior to that of twice-daily BUD/FM DPI for asthma maintenance therapy. FF/VI DPI treatment is more likely to improve inconvenience and forgetfulness in inhalation adherence barriers compared with BUD/FM DPI. As such, FF/VI DPI is a useful option for asthma maintenance treatment.

Publish your work in this journal

The Journal of Asthma and Allergy is an international, peer-reviewed open-access journal publishing original research, reports, editorials and commentaries on the following topics: Asthma; Pulmonary physiology; Asthma related clinical health; Clinical immunology and the immunological basis of disease; Pharmacological interventions and

new therapies. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <https://www.dovepress.com/journal-of-asthma-and-allergy-journal>
