## ABSTRACT

Auxin is a plant hormone that takes part in a series of developmental and physiological processes. There are three major gene families that play a role in the early response of auxin and auxin/indole-3-acetic acid (Aux/IAA) is one of these. Although the genomic organization and function of *Aux/IAA* genes have been recognized in reference plants there have only been a few focused studies conducted with non-model crop plants, especially in the woody perennial species. We conducted a genomic census and expression analysis of *Aux/IAA* genes in the cultivated apple (*Malus × domestica* Borkh.). The *Aux/IAA* gene family of the apple genome was identified and analyzed in this study. Phylogenetic analysis showed that *MdIAAs* could be categorized into nine subfamilies and that these *MdIAA* proteins contained four whole or partially conserved domains of the *MdIAA* family. The spatio-specific expression profiles showed that most of the *MdIAAs* were preferentially expressed in specific tissues. Some of these genes were significantly induced by treatments with one or more abiotic stresses. The overexpression of *MdIAA9* in tobacco (*Nicotiana tabacum* L.) plants significantly increased their tolerance to osmotic stresses. Our cumulative data supports the interactions between abiotic stresses and plant hormones and provides a theoretical basis for the mechanism of *Aux/IAA* and drought resistance in apples.

## INTRODUCTION

Auxins participate in diverse processes in the development and physiology of plants, including their cell division and differentiation, organogenesis, plant geotropic and phototropic responses, embryogenesis, apical dominance, root development, lateral root formation, axillary bud and lateral branch formation, leaf morphology, and vascular differentiation (Woodward & Bartel, 2005; Ljung, 2013). Ultimately, these processes are governed by the expression of an assortment of auxin-responsive genes (De Smet & Jürgens, 2007). The most prevalent and predominantly studied auxin, indole-3-acetic acid

(IAA), enhances the transcription of several classes of early genes, which includes small auxin-up RNA (SAUR), Gretchen Hagen3 (GH3), and auxin/indole-3-acetic acid (Aux/IAA) gene family members (Abel & Theologis, 1996). In the absence of auxin, Aux/IAA proteins act as transcriptional repressors at promoter sites of the auxin-responsive genes, at least in part by interfering with the activity of the auxin-response factor (ARF) transcriptional regulators. Once the auxin levels rise, the AUX/IAA proteins are degraded by poly ubiquitination and, subsequently, 26S proteasome, thus depressing ARF-mediated transcription (Tiwari et al., 2001).

Most Aux/IAA proteins have four conserved interaction domains (I–IV) (Hagen & Guilfoyle, 2002). Domain I contains an ERF-associated amphiphilic repression module that interacts with the TOPLESS (TPL) corepressor (Tiwari, Hagen & Guilfoyle, 2004; Oh et al., 2014). Domain II is associated with auxin transport inhibitor response 1; mutations occurring in this domain affect their interaction and results in a low auxin response (Gray et al., 2001). Domains III and IV are able to regulate hetero-dimerization with the other Aux/IAA family members, and interactions with ARF proteins (Ulmasov et al., 1997; Shen et al., 2010).

In 1982, the first Aux/IAA gene was identified in the soybean (*Glycine max*) (Walker & Key, 1982) and many more members of the Aux/IAA genes were subsequently reported by genome-wide analyses in *Arabidopsis* (*Arabidopsis thaliana*, 34 genes), maize (*Zea mays* L., 34 genes), rice (*Oryza sativa* L., 31 genes), cucumber (*Cucumis sativus* L., 27 genes), tomato (*Solanum lycopersicon*, 26 genes), Chinese hickory (*Carya cathayensis* Sarg., 22 genes), papaya (*Carica papaya* L., 18 genes) and *Medicago* (*Medicago truncatula*, 17 genes) (Liscum & Reed, 2002; Wu et al., 2012, 2014; Yuan et al., 2018; Wang et al., 2010b; Shen et al., 2014; Jain et al., 2006; Liu et al., 2017). In *Arabidopsis*, the function of several Aux/IAA genes have been characterized by their corresponding mutants. IAA7, IAA17, IAA19, and IAA28 are involved in determining the numbers of lateral roots, whereas IAA14 is necessary for the formation of the lateral roots (Fukaki et al., 2002). In tomatoes, SlIAA9 has been shown to play multiple roles in the development of the leaf shape and fruit (Wang et al., 2005), while SlIAA15 assists in the formation of the axillary buds and the epidermis (Deng et al., 2012). In potatoes (*Solanum tuberosum* L.), the down regulation of StIAA2 results in a greater plant height and petiole hyponasty (Kloosterman, Visser & Bachem, 2006). In rice, OsIAA6 is highly induced by drought stress and its overexpression (OE) in transgenic rice improves drought tolerance (Jung et al., 2015).

Apples (*Malus × domestica* Borkh.) are a fruit crop that is cultivated throughout the world, occupying an important economic position in the world's fruit production (Dong et al., 2018a). Apple breeding focuses on improving the stress resistance of this crop as biological and abiotic stresses are key factors in the distribution and yield of apple trees (Mao et al., 2017). However, the GH3 gene family is currently the only one to have been investigated in the apple (Yuan et al., 2013). Previous studies have shown that specific Aux/IAA genes are involved in fruit development, maturation, and drought stress responses (Liu et al., 2017). However, MdIAAs have not been well studied under the background of abiotic stress response. Here, we have identified 34 Aux/IAA genes in the apple. Our goal was to document their chromosomal location, intron-exon structure,

cis-element composition, and expression under development and stress. Additionally, we describe the corresponding protein domain architecture and phylogenetic relationships among the apple Aux/IAAs and those from other plants. This study also investigated the function of *MdIAA9* by overexpressing *MdIAA9* in tobacco. Our work provides a valuable resource for further investigating the functional mechanisms of *MdIAAs* in modulating the abiotic stress tolerance of the apple.

## MATERIALS AND METHODS

### Plant materials and treatments

Tissue-specific expression was monitored in the young roots, stems, fully expanded leaves, flowers, and mature fruits from 5-year-old apple plants that had been treated with bud grafting. The apple plant was the combination of a scion (*Malus domestica* Golden Delicious) and a stock plant (*Malus hupehensis*). To vary the treatments, 1 year-old plants (Golden Delicious scions and *Malus hupehensis* rootstocks) were grown in pots (diameter: 300 mm, height: 320 mm) in a greenhouse. One seedling was grown per pot and 60 pots were used per treatment. In order to achieve drought stress, irrigation for the seedlings was discontinued when the plant height reached approximately 0.5 m. The 9th–12th leaves were collected from the base of the plants when irrigation had been withheld for 0, 2, 4, 6, 8, and 10 days. A 200 mM sodium chloride (NaCl) solution was used to irrigate plants using a salt stress treatment and the samples were collected at 0, 1, 5, 10, 15, and 20 days after irrigation. For chilling treatments, plants were put into phytotrons (24 h-constant illumination and photosynthetic photon flux of  $270 \mu\text{mol}\cdot\text{m}^{-2}\cdot\text{s}^{-1}$ ), the temperature was adjusted to 4 °C and the samples were collected at 0, 2, 4, 8, 12, and 24 h. For abscisic acid (ABA) and IAA treatments, plants were sprayed with 100 mM ABA or 10  $\mu\text{M}$  IAA and the samples were collected at 0, 2, 4, 8, 12, and 24 h. The samples were frozen immediately in liquid nitrogen, then stored at –80 °C until RNA analysis occurred. The seedlings of the wild type (“NC89” tobacco) were used for genetic transformations. Transgenic plants and wild types were cultured in a growth chamber under a 16-h photoperiod at 23 °C. A total of 15 day old plants were grown on Murashige and Skoog (MS) agar medium supplemented with 0 or 200 mM of mannitol and left to grow for 13 day for the assay of osmotic stress. Seedling growth parameters, such as root lengths, fresh weights, and relative electrolyte leakage (REL), concentrations of chlorophyll, malondialdehyde (MDA), and proline were then measured. All of the experiments were repeated three times.

### Identification of apple Aux/IAA genes

Annotated Aux/IAA open reading frame (ORF) translations from *Arabidopsis* were obtained by searching the TAIR website (TAIR10; <http://www.arabidopsis.org/>) (Dong *et al.*, 2018a). A total of 34 *Arabidopsis* Aux/IAA sequences were used as queries in a homology search of annotated ORF translations from the Genome Database for Rosaceae (GDR; <http://www.rosaceae.org/>) (Tian *et al.*, 2015) using the Basic Local Alignment Search Algorithm (<https://www.rosaceae.org/blast>). In addition, we searched the annotated apple ORF translations using a Hidden Markov Model-based approach

(HMMER v3.0) and the Aux/IAA domain signature PF02309 as maintained by the Pfam database (<http://pfam.xfam.org/family/PF02309>). The presence of Aux/IAA domains was confirmed in each candidate MdIAA sequence using the Pfam database (<http://pfam.sanger.ac.uk/search>) and NCBI-Conserved Domain Search (<http://www.ncbi.nlm.nih.gov/Structure/cdd/wrpsb.cgi>) *Shao et al. (2014)* (*Dong et al., 2018b*).

### Multiple sequence alignments, phylogenetic analysis, and exon/intron organization of MdAux/IAA proteins

Multiple sequence alignments were performed for 34 MdIAA protein sequences using DNAMAN 6.0.3.99 with default parameters (*Zhou et al., 2017*). Full-length protein sequences of *Arabidopsis* and rice were obtained from the NCBI protein database. The phylogenetic trees were estimated with the MEGA6 program (*Dong et al., 2018b*) using the neighbor-joining method (*Saitou & Nei, 1987*) with Poisson corrections and 1,000 replications for the bootstrap analysis. Genomic sequences and location data in apples were observed from the apple genome database (<https://www.rosaceae.org/organism/Malus/x-domestica>; Genome version 1.0). The structural features of these MdIAA genes which included exons/introns, exon numbers, and locations were obtained and shown using TBTools.

### Cloning of MdIAAs and gene expression analysis

Total RNA was extracted from frozen samples using the cetyl trimethyl ammonium bromide method (*Wang et al., 2017a*). Two µg of total RNA was used for synthesizing the first-strand cDNA. MdIAA ORF sequences were obtained using RT-PCR, with fully expanded leaves from the Golden Delicious apple as an RNA source, in addition to 17 gene-specific primer pairs as listed in Table 1. For quantitative real time PCR (qRT-PCR) assays, gene-specific primers were designed and synthesized by Sangon Biotech (Shanghai, China). One µg of total RNA from each sample was used to perform reverse transcription and one µL of the product was used for PCR-amplification. All reactions contained 10 µL of SYBR® Premix Ex Taq™ (TaKaRa, Kusatsu, Japan), 0.4 µL of each specific primer, 8.2 µL of ddH<sub>2</sub>O, and 1.0 µL of cDNA template, and the reactions were run by an iQ5 instrument (Bio-Rad, Hercules, CA, USA) (*Dong et al., 2018a*). The PCR conditions included an initial 95 °C for 3 min, then 40 cycles of 95 °C for 10 s, 58 °C for 30 s, and 72 °C for 15 s; this was followed by 72 °C for 3 min and then 81 cycles of 7 s each, increasing by an increment of 0.5 °C from 55 to 95 °C. Three biological replicates were conducted for each treatment and the values of ΔCt were calculated using the MdMDH gene or NtActin as the endogenous control (*Wang et al., 2017b*). The relative expression levels of MdIAA genes were obtained according to the  $2^{-\Delta\Delta Ct}$  method (*Livak & Schmittgen, 2001*) and the specificity of the amplifications was examined by dissociation curve analysis.

### Prediction of cis-acting elements in promoters

The upstream regions (1,500 bp upstream of the translational start codon) of the selected MdIAAs were used to identify putative cis-acting elements (Plant CARE database; <http://bioinformatics.psb.ugent.be/webtools/plantcare/html/>) (*Wang et al., 2017a*).

## Vector construction and plant transformation

In order to isolate the full-length cDNA of *MdIAA9* used to construct the OE vectors, we conducted RT-PCR using fully expanded Golden Delicious apple leaves. The cDNA of *MdIAA9* was cloned into pBI 121 vectors and was driven by a 35S promoter known as the cauliflower mosaic virus. For tobacco transformation, wild type (“NC89” tobacco) plants were transformed using the *Agrobacterium tumefaciens* EHA105-mediated leaf dip method (Xia *et al.*, 2012). The PCR-positive plantlets were transplanted into soil for growing in the greenhouse. Seeds were screened with 50 mg L<sup>-1</sup> kanamycin after the transgenic plants were harvested individually. Homozygous transgenic T3 plants were used in osmotic stress investigations.

## Measurement of physiological indices

Relative electrolyte leakage was determined according to the method described by Tan *et al.* (2017). Chlorophyll concentrations and free proline were measured using the method of Dong *et al.* (2018a), and MDA levels were measured as described by Wei *et al.* (2018).

## Statistical analysis

The experimental data obtained was analyzed using SPSS 20 software (SPSS, Inc., Chicago, IL, USA) and indicated by means ± standard deviation. Data was analyzed using One-way ANOVA and Tukey’s tests at a significance level of  $P < 0.05$ .

# RESULTS

## Aux/IAA gene family members in apple

In order to identify AUX/IAA proteins in apples, 34 *Arabidopsis* Aux/IAA proteins were used to search the apple genome database by BLASTP. In addition, we carried out a Hidden Markov Model search based on the AUX/IAA domain signature. In all, 35 candidate genes were found. In order to further confirm and identify the conserved Aux/IAA domains, all candidate proteins were analyzed using Pfam and SMART databases. One gene, *MD15G1305900*, was not analyzed further because it contained an apparently incomplete reading frame. We obtained basic information for the remaining 34 Aux/IAA genes, which included gene names, locus IDs, intron numbers, ORF lengths, chromosome locations, and numbers of amino acids (Table 2). The ORF lengths of MdIAAs ranged from 498 base pairs (*MdIAA19*) to 1,158 base pairs (*MdIAA34*), with an average length of 789 base pairs. The size of MdIAA proteins were found to have a range of 165–385 amino acids. The corresponding molecular mass varied from 18.21 kD (*MdIAA19*) to 40.61 kD (*MdIAA34*).

## Phylogenetic relationships of Aux/IAA proteins

A phylogenetic tree was constructed which included 34 members in apple, 34 members in *Arabidopsis*, and 31 members in rice. According to their phylogenetic relationships, Aux/IAA members of the three species could be split into nine subgroups, which were numbered I–IX (Fig. 1). The number of MdIAAs in the nine subgroups ranged from four to 17. The 34 MdIAAs were distributed unevenly among the subgroups. The numbers of MdIAAs in Subgroups I, II, III, IV, V, VI, VII, VIII, and IX were 4, 2, 4, 4, 1, 2, 6, 3, and 8, respectively.

### Sequence alignment, gene structure, and conserved motifs of Aux/IAA proteins in apple

There were four conservative domains from a sequence alignment of the ORF translation of the Aux/IAA genes (Fig. 2). Nuclear localization signals were also found in most MdIAAs. Amino acids at five positions were absolutely conserved among all MdIAAs,

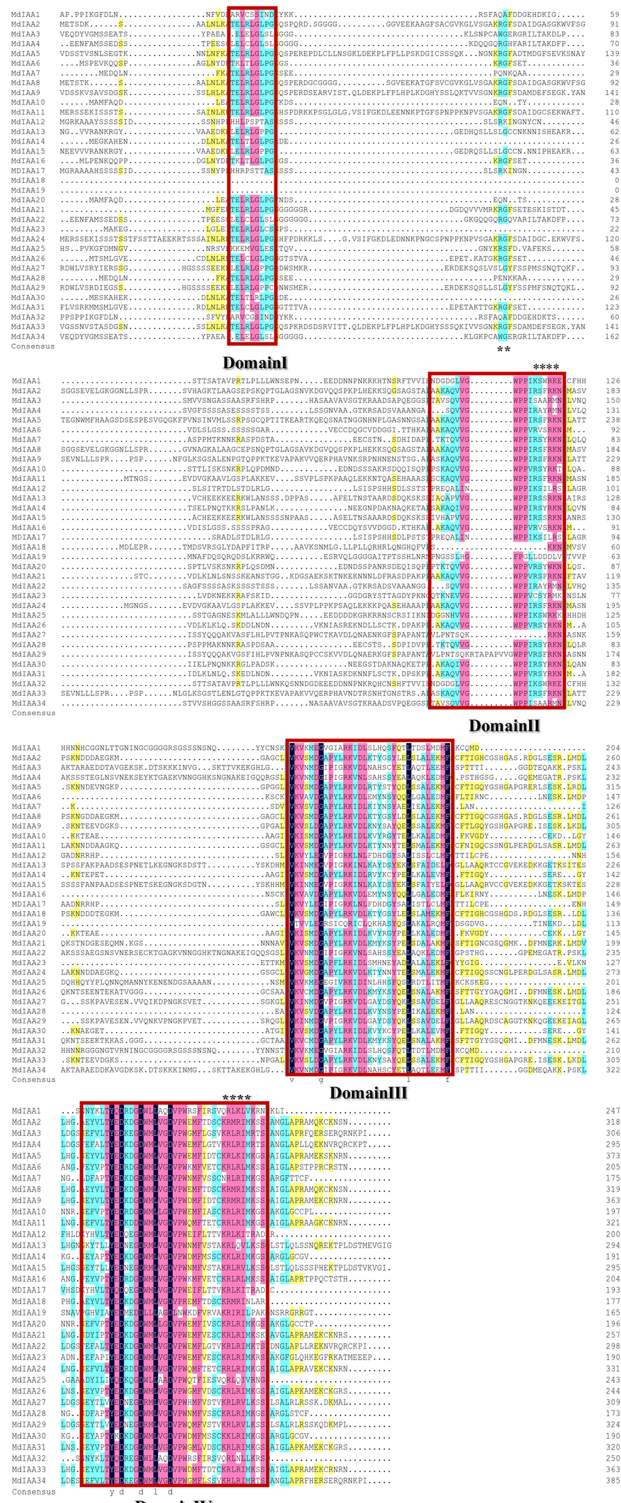

**Figure 1** Phylogenetic analysis of 99 AUX/IAA proteins from apple, rice, *Arabidopsis*. The phylogenetic tree was generated using MEGA 6.0 with the Neighbor-Joining (NJ) method with 1,000 bootstrap replicates. Aux/IAA members of the three species could be split into nine subgroups, which were numbered I–IX. [Full-size !\[\]\(5fd6ef84f97f42d7f8b34275f1b65312\_img.jpg\) DOI: 10.7717/peerj.7935/fig-1](https://doi.org/10.7717/peerj.7935/fig-1)

but amino acids in 30 positions were strongly conserved (75–99%). The similarity between the other amino acids was <50%.

To explore the *MdIAA* gene's structural diversity in apples, we evaluated the conservation of the exon-intron organization. The *MdIAA* proteins were divided into groups I and II according to their phylogenetic relationships (Fig. 3). The gene structure analysis suggested that in group I, although *MdIAA18* had one exon and the other two genes (*MdIAA9* and *MdIAA33*) had six exons, most genes had four exons. In group II, only *MdIAA19* contained two exons and the remaining genes contained four exons.

We identified common motifs using the MEME web server (<http://meme-suite.org/tools/meme>) (Fig. 4). The following parameter settings were used: size distribution, zero or one occurrence per sequence (zoops); motifs count, 4; and motif width, between six and

**Figure 2** Amino acid sequence alignment and domain analysis of MdIAA family proteins. Multiple alignments were conducted for protein acid alignment and domain analysis among the MdIAA family proteins by using the DNAMAN program. The similar amino acids among the proteins were highlighted with different colors. Four domains of MdIAA proteins were marked with red frames. Nuclear localization signals (NLS) are indicated with black asterisks. [Full-size !\[\]\(fcc3264021d438d9732560e78099f674\_img.jpg\) DOI: 10.7717/peerj.7935/fig-2](https://doi.org/10.7717/peerj.7935/fig-2)

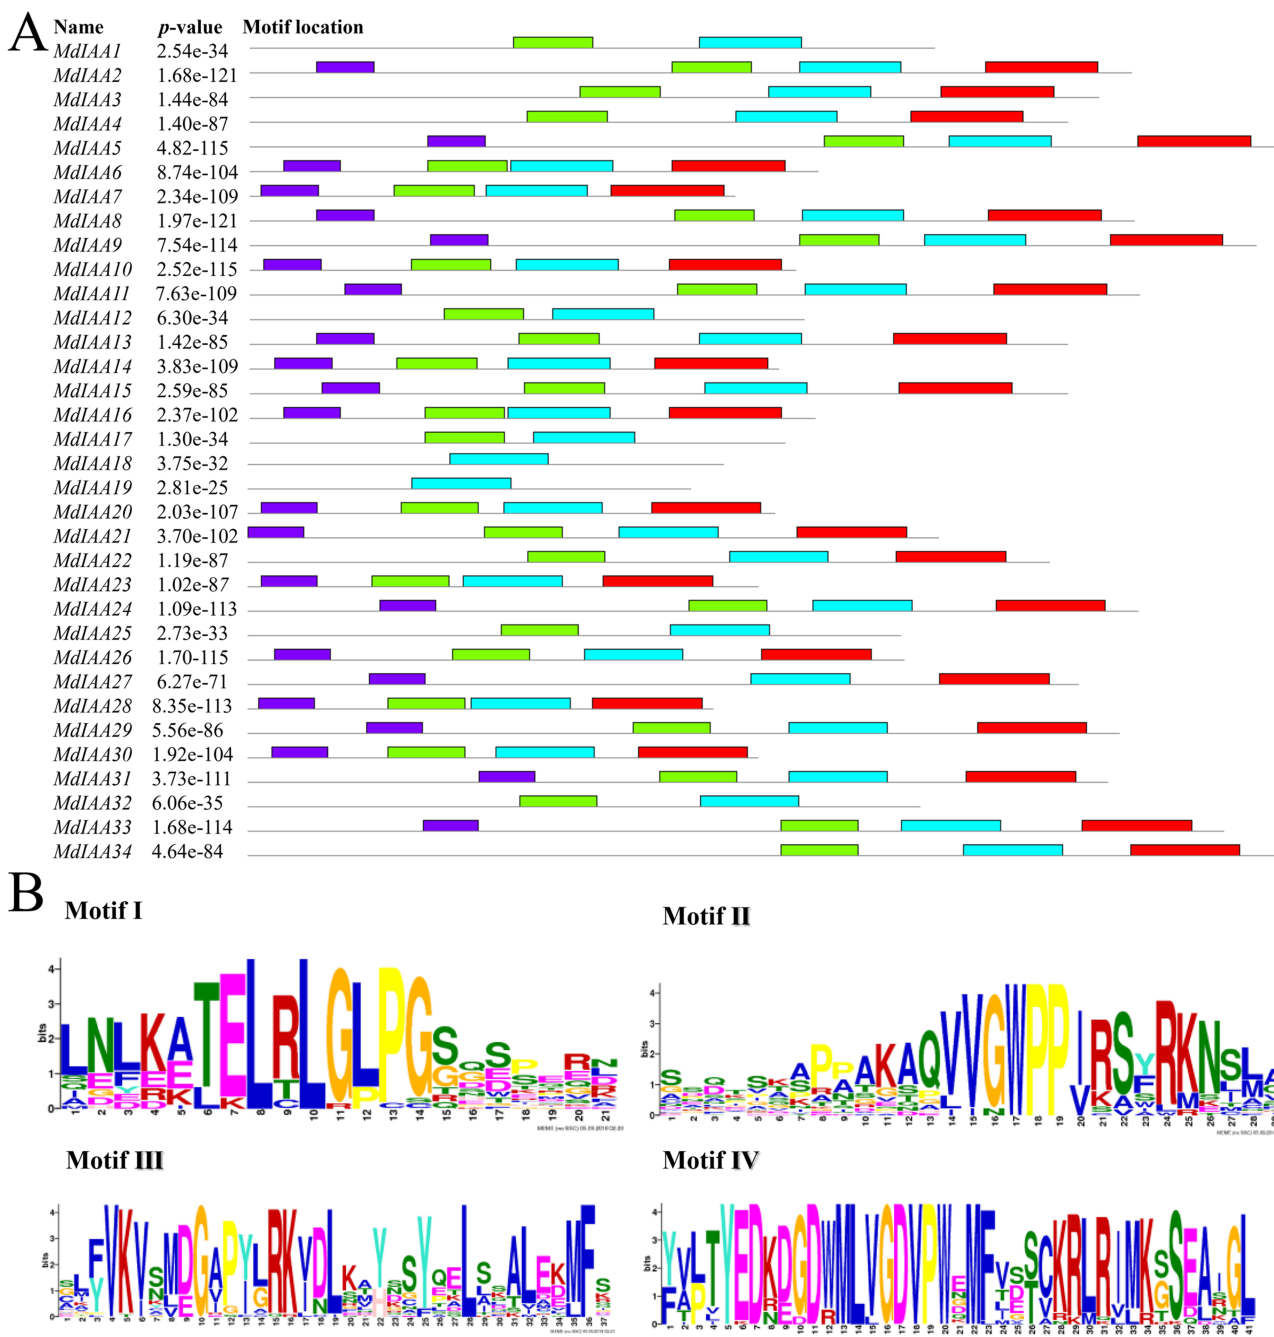

**Figure 3** Phylogenetic relationships and structures for 34 MdIAAs. The phylogenetic tree for full-length amino acid sequences was constructed with MEGA software and the NJ method. Aux/IAA members of apple could be split into two subgroups, which were numbered I and II. The exons and introns are represented by green boxes and lines, respectively. The 5'- and 3'-untranslated regions (UTRs) are represented by yellow boxes.

50 wide. In our research, the four motifs identified by MEME were consistent with the four classical domains. This identified four motifs, which corresponded to the four conserved domains found through sequence alignment above. All four motifs were apparent in 22 of the proteins, although only three motifs were found in seven additional proteins. Motif I was not contained in MdIAA3, MdIAA4, MdIAA22, and MdIAA34; Motif IV was not in MdIAA12 and MdIAA4; and Motif II was not in MdIAA27. Three MdIAAs, MdIAA1, MdIAA25, and MdIAA32, contained only Motif II and Motif III, and two other MdIAAs, MdIAA18 and MdIAA19, contained only Motif II. It is obvious that most of the domains and motif regions overlapped with each other. Additionally, several highly conserved key sequences, such as LxLxLx in Domain I and Motif I, and VGWPP in Domain II and Motif II, strongly suggests that these regions may be the key sites conferring the functions of MdIAAs.

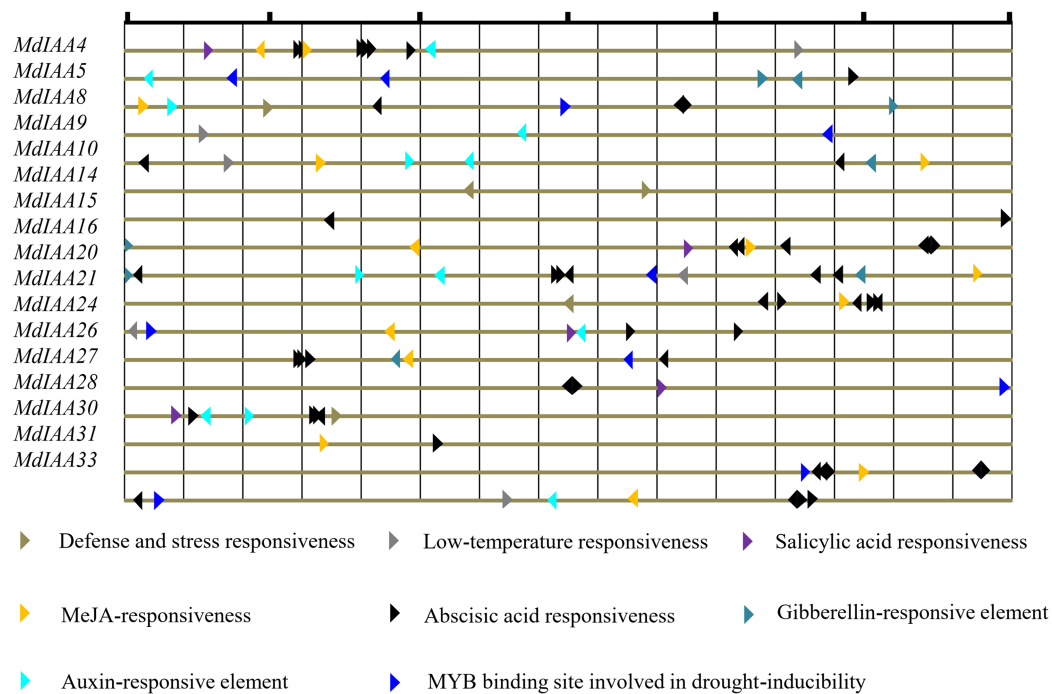

### Cloning of apple IAA genes

To confirm the coding sequence of MdIAAs as annotated in the reference genome and to further uncover the biological function of these MdIAAs, 17 *MdIAA* genes were cloned: *MdIAA4*, *MdIAA5*, *MdIAA8*, *MdIAA9*, *MdIAA10*, *MdIAA14*, *MdIAA15*,

**Figure 4** The motif distribution of the MdIAA proteins. (A) Shows 4 classical motifs I, II, III, and IV (labelled by different color blocks) of the Aux/IAA proteins, which were analyzed by the Multiple Expectation Maximization for Motif Elicitation (MEME) web server. (B) The degree of specific amino acids conservation in each motif of Aux/IAA varies with the height of each letter. [Full-size !\[\]\(ba1b80118482ccef74a5d718ca4d7242\_img.jpg\) DOI: 10.7717/peerj.7935/fig-4](https://doi.org/10.7717/peerj.7935/fig-4)

*MdIAA16*, *MdIAA20*, *MdIAA21*, *MdIAA24*, *MdIAA26*, *MdIAA27*, *MdIAA28*, *MdIAA30*, *MdIAA31*, and *MdIAA33*, respectively. As a result, all cloned sequences showed a high similarity to the predicted apple genome (Data S1). The sequences were submitted to NCBI GenBank.

**Figure 5** The main putative cis-elements within 1.5 kb upstream promoter regions of *MdIAAs*. The different cis-elements are shown by using different icons and colors. The direction of the apex angle to the right indicates the cis-acting element in the (+) strand, and the direction of the apex angle indicates to the left the cis-acting element in the (-) strand. [Full-size !\[\]\(5f471a71b78d7676bc356df190b88ab4\_img.jpg\) DOI: 10.7717/peerj.7935/fig-5](https://doi.org/10.7717/peerj.7935/fig-5)

### Analysis of promoter cis-elements of apple *IAA* genes

Promoter cis-regulatory elements are of great significance in regulating gene expression. In this study, the putative cis-elements within the *MdIAA* promoter (<1.5 kb upstream from the start site of putative translation) were identified through the PlantCARE database (Fig. 5) and different kinds of cis-elements related to stress and hormone responses were identified. Most *MdIAA* promoters contained ABRE elements, which usually participate in ABA related responses. Nine of the *MdIAA* genes contained a TGA-box, which is an auxin-responsive element. Six of the *MdIAA* genes contained gibberellins-responsive elements such as P-box, GARE-motif or TATC-box. A total of 11 of the *MdIAA* genes contained a G-box, CGTCA-motif, and/or TGACG-motif, which participate in JA/MeJA-responses. Five of the *MdIAA* genes contained a TCA-element, which is related to salicylic acid responsiveness. A large number of putative hormone-responsive elements suggested that these genes were involved in hormone signal transduction. Moreover, the promoters contained drought-inducibility elements (MBS), low-temperature response motifs (LTR), and defense and stress responsiveness elements (TC-rich repeats). The results indicated that *MdIAA* genes may be involved in defense signaling and biotic and abiotic stress in apple plants.

### The spatio-specific profiles of *MdIAA* genes expression in various tissues

In order to determine the additional roles that *MdIAAs* play in growth and development, 17 selected *MdIAA* genes were examined in the roots, stems, leaves, flowers, and fruits

**Figure 6** Expression profiles of *MdIAA* genes in various tissues. Heat map of *MdIAA* genes expression in flowers, fruit, leaves, roots, and stems of apple plants generated by using TIGR MeV v4.8.1 software. Levels of down-regulated expression (green) or up-regulated expression (red) are shown on a  $\log^2$  scale from the highest to the lowest expression for each *MdIAA* gene.

Full-size  DOI: [10.7717/peerj.7935/fig-6](https://doi.org/10.7717/peerj.7935/fig-6)

using qRT-PCR. Some *MdIAAs* showed higher expressions in multiple tissues (Fig. 6). For instance, there were high levels of expression of *MdIAA20* and *MdIAA33* in all of the examined tissues. The expression of *MdIAA20* was the highest in flowers and fruit while the expression of *MdIAA33* was the highest in the roots, stems, and leaves. In addition, a higher transcriptional accumulation in the flowering and fruiting stages of *MdIAA4*, *MdIAA9*, and *MdIAA24* were found, suggesting that they may play specific roles in the development of flowers and fruit. The mRNA abundances of the *MdIAA* family genes were higher in fruit than in other tissues. Furthermore, the expression of *MdIAA* genes in the stems was the lowest among all the tissues. These results indicated that *MdIAA* genes might play roles in fruit. Overall, the tissue-specific spatial differential expression of *MdIAA* suggests that these genes were specifically related to apple growth and development.

### Expression profiles of *MdIAA* genes following IAA treatment

It is well known that auxin induces the strong expression of the *Aux/IAA* genes (Liu *et al.*, 2017). qRT-PCR was performed to confirm the response of the *MdIAA* genes following IAA treatment. In this work, five testing time points (0, 2, 4, 8, 12, and 24 h) were selected. Under IAA treatment, the *MdIAA* family genes displayed various expression styles. The expressions of the majority of the *MdIAA* genes were up-regulated at 4 h as compared with controls (Fig. 7), but the expressions of most *MdIAA* genes were down-regulated at 8 and 12 h as compared with controls. No significant changes in gene expression were observed in other genes, such as *MdIAA27*, after IAA treatment. Taken together, this data indicated that most genes from the *MdIAA* family were auxin early-response genes.

**Figure 7** The expression patterns of *MdIAAs* in apple under auxin treatments. Samples were harvested at 0, 2, 4, 8, 12, and 24 h after foliar application. Error bars show standard deviations of three biological replicates. Asterisks indicate a significant difference ( $*P < 0.05$ ) compared with the corresponding controls, based on one-way ANOVA and Tukey's tests.

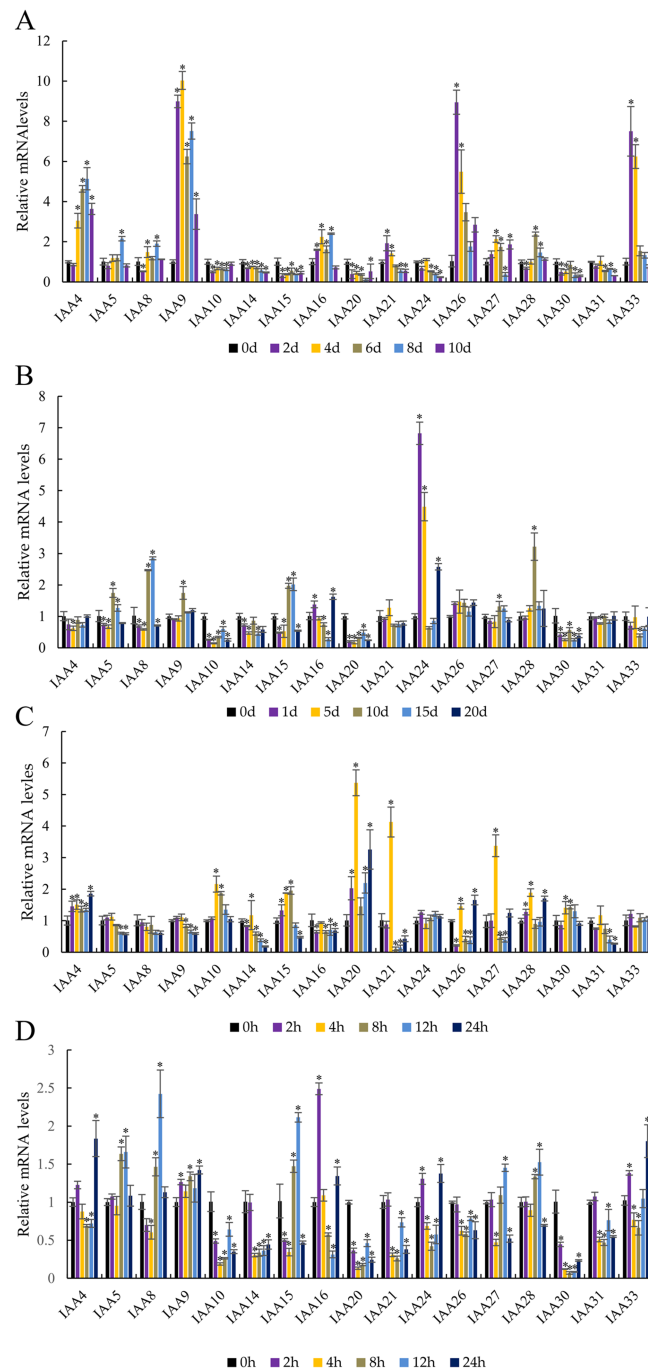

Full-size DOI: 10.7717/peerj.7935/fig-7

## The profiles of *MdIAA* gene expression following abiotic stresses and ABA spray

To investigate the effects of abiotic stresses and ABA treatment on *MdIAA* gene expression, the patterns of transcription were observed after drought, cold, NaCl, and ABA treatment (Fig. 8). Under drought stress, the expressions of *MdIAA* genes showed diverse responses at different time points (Fig. 8A). Among the 17 *MdIAA* selected genes, *MdIAA4*, *MdIAA26*, and *MdIAA33* increased significantly. The expression of *MdIAA4* was 5.15 times that of the control group at 8 days of drought treatment and the expression of *MdIAA26* was 8.95 times that of the control group at 2 days and 5.50 times that at 4 days of drought treatment, respectively. The expression levels of *MdIAA33* showed a trend similar to *MdIAA26*, being 7.50 times and 6.24 times that of the control group at 2 and 4 days, respectively. However, in this study, the expression levels of several *MdIAA* genes were significantly lower than those of the control group after drought treatment. For instance, the expression of *MdIAA20* was only 12.7% of the control group at 8 d under drought treatment, while the expression of *MdIAA24* was only 23.8% of the control group at 10 days under drought treatment.

Two genes showed an obvious response to the NaCl treatment (Fig. 8B). The expression of *MdIAA24* was 6.82 and 4.49 times that of the control group at 1 and 5 days, respectively, but the expression of *MdIAA28* was 3.22 times that of the control group at 15 days. However, some *MdIAA* gene expression was dramatically reduced after NaCl treatment. For example, the expression of *MdIAA10* and *MdIAA20* was only 14.1% and 17.7% of the control group, respectively.

In response to chilling at 4 °C, three *MdIAA* genes, *MdIAA20*, *MdIAA21*, and *MdIAA27*, increased significantly at 4 h of treatment (Fig. 8C). However, their expressions were then down-regulated over time. For example, at 8 h, *MdIAA21* was only 10.82% of the control group. The other genes, such as *MdIAA24* and *MdIAA33*, showed no alterations in expression under most conditions.

**Figure 8** Abiotic stress altered expression of selected IAA genes in apple leaves. (A) Drought: samples were collected at 0, 2, 4, 6, 8, and 10 days after withdrawal irrigation. (B) NaCl treatment: samples were harvested at 0, 1, 5, 10, 15, and 20 days after irrigation with 200 mM NaCl solution. (C) Chilling challenge: samples were harvested at 0, 2, 4, 8, 12, and 24 h after exposure to 4 °C. (D) ABA (100 μM): samples were harvested at 0, 2, 4, 8, 12, and 24 h after foliar application. Error bars show standard deviations of three biological replicates. Asterisks indicate a significant difference ( $*P < 0.05$ ) compared with the corresponding controls, based on one-way ANOVA and Tukey's tests.

Full-size DOI: [10.7717/peerj.7935/fig-8](https://doi.org/10.7717/peerj.7935/fig-8)

**Figure 9** PCR identification and relative expression analysis of *MdIAA9* in wild-type and transgenic tobacco lines. (A) 35S and *MdIAA9-R* indicate that the primers used to identify the transgenic lines were designed according to the *MdIAA9*. M, DNA marker; –, negative control (H<sub>2</sub>O); +, positive control (plasmid DNA of 35S::*MdIAA9* pBI121 vector). (B) Specific primers for *MdIAA9* were used to detect relative expression levels of WT and transgenic tobacco lines.

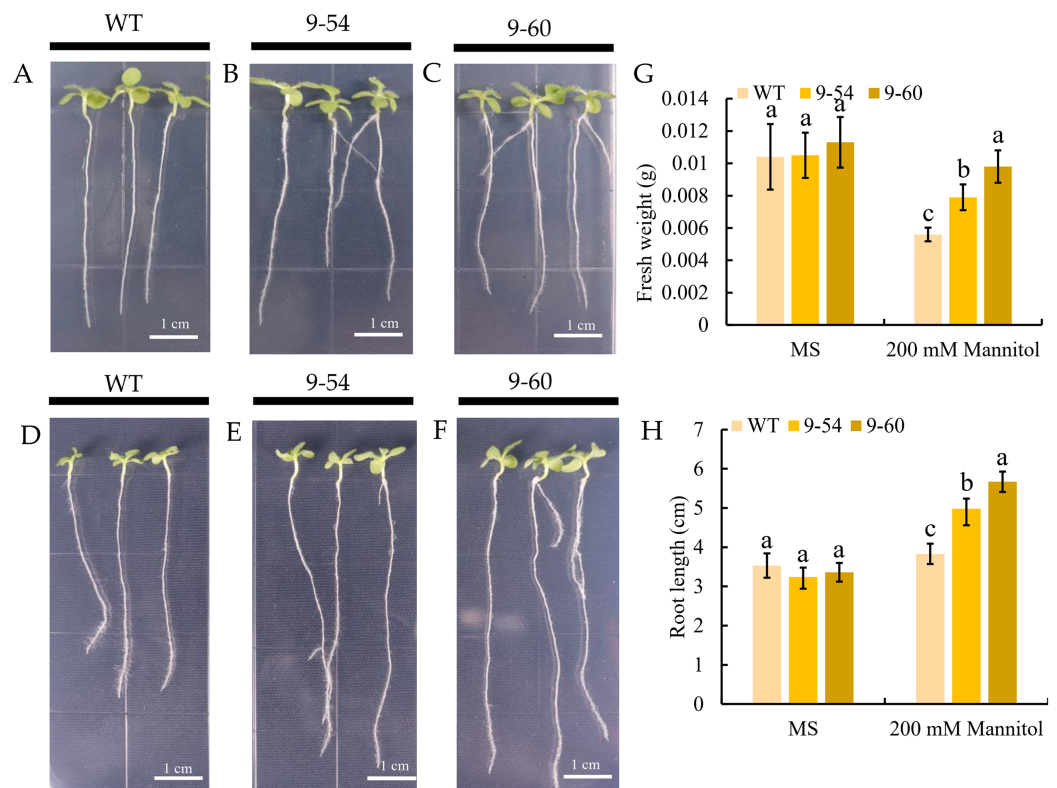

Full-size DOI: 10.7717/peerj.7935/fig-9

After ABA application (Fig. 8D), the expressions of *MdIAA10*, *MdIAA14*, *MdIAA20*, *MdIAA21*, and *MdIAA30* decreased significantly. Among these genes, *MdIAA30* changed most dramatically, and was only 7.05% of the control group at 8 h although some genes increased significantly during this time. For instance, the expression of *MdIAA25* was 2.50 times that of the control group at 2 h whereas *MdIAA8* was 2.42 times that of the control group at 12 h. Hence, these genes were designated as being ABA-responsive.

### Overexpression of *MdIAA9* enhanced plant growth of tobacco seedlings under osmotic stress

Under drought stress, *MdIAA9* was significantly up-regulated, so we chose this gene to study its biological function in tobacco. Two transgenic lines were identified at the DNA level, using 35S promoter positive primers and the reverse primers of *MdIAA9* (Table 2; Fig. 9). We examined the root length and fresh weights of transgenic and wild plants under osmotic stress. Our results showed that the root lengths and fresh weights of the transgenic plants were significantly higher than those of the wild types under osmotic stress.

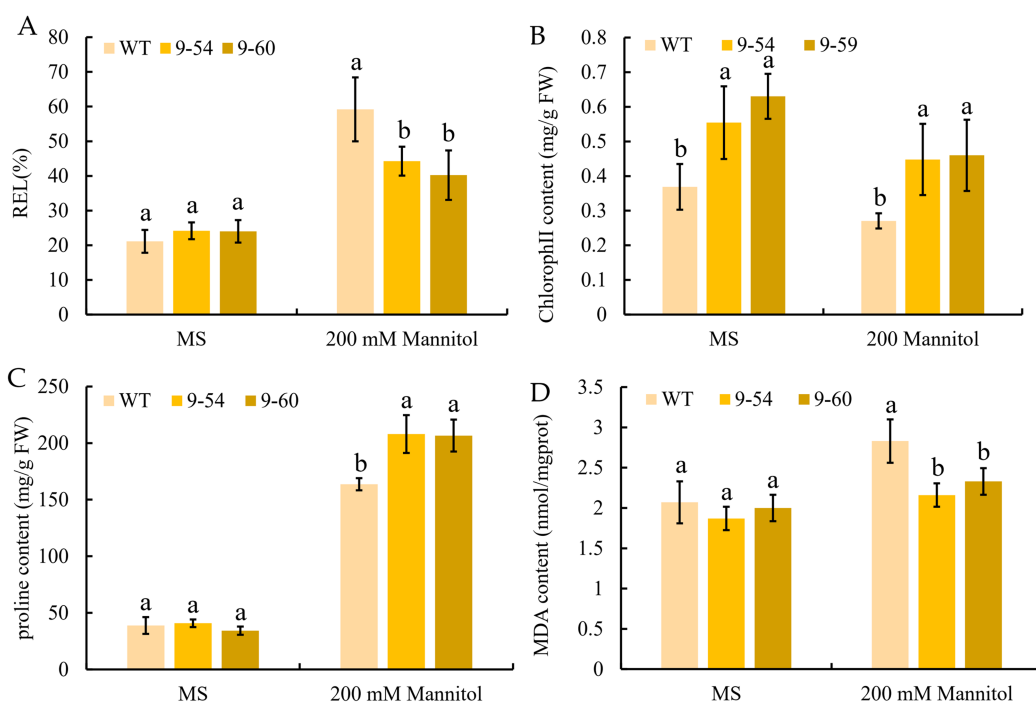

**Figure 10** Comparative analysis of *MdIAA9*-overexpressing tobacco seedlings and wild type in response to mannitol treatment. (A–C) Representative images of wild type and *MdIAA9*-overexpressing seedlings grown vertically in MS medium contained zero mM mannitol for 13 days. (D–F) Representative images of wild type and *MdIAA9*-overexpressing seedlings grown vertically in MS medium contained 200 mM mannitol for 13 days. Bars = 1 cm. (G) Fresh weights between WT and transgenic lines after exposure to osmotic stress for 13 days. (H) Comparison of primary root lengths between WT and transgenic lines after exposure to osmotic stress for 13 days. Error bars represent standard deviations from three biological replicates. For (G) and (H) different letters that follow the values indicate significant differences between treatments at  $P < 0.05$ , based on one-way ANOVA and Tukey's tests. [Full-size DOI: 10.7717/peerj.7935/fig-10](https://doi.org/10.7717/peerj.7935/fig-10)

However, no significant difference was observed between the transgenic and wild plants under the control conditions (Fig. 10).

### Analysis of physiological characteristics of *MdIAA9*-overexpressing tobacco seedlings and wild type to osmotic stress

To further study the enhancement of osmotic stress tolerance mediated by *MdIAA9*, the REL, chlorophyll concentration, proline, and MDA concentrations were determined. These are important markers to measure the degree of osmotic stress injury. Under normal conditions, no significant difference was observed between the transgenic and wild plants. However, the REL values of the wild lines were significantly higher than the overexpressing tobacco seedlings under 200 mM mannitol conditions (Fig. 11A). The chlorophyll levels of wild and overexpressed plants were similar under both the osmotic stress and normal conditions. The quantities of proline in transgenic plants were significantly higher than the wild line under 200 mM mannitol, but no significant

**Figure 11** Response to osmotic stress in transgenic and wild tobacco seedlings. (A) relative electrolyte leakage (REL), (B) chlorophyll content, (C) proline content, and (D) MDA content in transgenic and WT seedlings after exposure to MS medium contained 0 or 200 mM mannitol for 13 days. Error bars represent standard deviations from three biological replicates. For (A–D), different letters following the values indicate significant differences between treatments at  $P < 0.05$ , based on one-way ANOVA and Tukey's tests. Full-size DOI: 10.7717/peerj.7935/fig-11

differences were revealed under normal conditions between the transgenic and wild plants (Figs. 11B and 11C). Furthermore, the MDA content of the transgenic plants was significantly lower than the wild plants under the 200 mM mannitol conditions, while no significant difference was observed in the transgenic lines and wild types under normal conditions (Fig. 8D). The results suggested that the OE of *MdIAA9* in tobacco seedlings leads to a higher tolerance of osmotic stress.

## DISCUSSION

Indole-3-acetic acid, a key signaling molecule, plays a vital role in a series of processes during plant growth and development (Liu *et al.*, 2015). Aux/IAA inhibits downstream gene expression through its interaction with ARFs (Liu *et al.*, 2015; Yu *et al.*, 2017; Kalluri *et al.*, 2007). Plants are subjected to environmental stresses such as drought, salinity, and low temperature, adversely affecting their growth and development (Tan *et al.*, 2014). Auxin-responsive genes are thought to participate in various responses related to environmental stress (Guo *et al.*, 2018; Shani *et al.*, 2017).

Many family members of Aux/IAA genes have been identified to date from different plant species such as *Arabidopsis*, tomato, rice, *Medicago*, and papaya (Yuan *et al.*, 2018; Wang *et al.*, 2010b; Shen *et al.*, 2014; Wu *et al.*, 2014; Jain *et al.*, 2006). The characterization and expression analysis of the *MdIAA* genes help investigators to further understand

the involvement of auxin in various types of stress. However, in the apple, there is little known about *IAA* genes or their expression. A total of 34 *MdIAA* genes were identified in this study, which are as many as have been identified in *Arabidopsis*.

We found that most of the *MdIAA* proteins possessed four classically conserved domains. The comparison of those conserved domains showed that 10 *MdIAA* genes (*MdIAA1*, *MdIAA3*, *MdIAA4*, *MdIAA12*, *MdIAA17*, *MdIAA18*, *MdIAA19*, *MdIAA22*, *MdIAA25*, and *MdIAA34*) lacked Domain I, which acts as a repressor in the signaling pathway of auxin. The *MdIAA* proteins contained Domain II (except for *MdIAA18*, *MdIAA19*, and *MdIAA27*), which was necessary for the protein degradation process mediated by auxin (*Dharmasiri, Dharmasiri & Estelle, 2005*). It is noteworthy that all *MdIAA* proteins contained Domain III and most of *MdIAA* proteins contained Domain IV. Our results suggested that most *MdIAAs* might interact with ARFs by forming stable homo- and hetero-dimers.

The *Arabidopsis* and rice *Aux/IAA* gene families have been well characterized. Useful information will be provided about the biological functions of the apple through comparative studies on phylogenetic relationships. We concomitantly monitored the expression patterns of 17 *MdIAA* genes from different apple tissues. Plants floral initiation is an important stage in their life cycle. In *Arabidopsis*, the gain-of-function mutant *IAA7/AXR2* confers delayed flowering under short-day light (*Mai, Wang & Yang, 2011*). Interestingly, *MdIAA21*, a homologous gene of *AtIAA7*, was highly expressed in flowers (*Fig. 4*), which suggested that *MdIAA7* might play an important role in the apple flowering process. However, *AtIAA14* proved to have an important role in the development of both lateral and adventitious root development (*Lopez-Bucio et al., 2015*). The orthologous gene of *AtIAA14* in apple, *MdIAA21*, was preferentially expressed in the flowers, which indicated that the apple *IAA* family genes may vary in the evolution for their own growth and development. Furthermore, a phylogenetic tree was constructed to reveal the evolutionary relationships of *IAA* genes between apple and rice. Interestingly, in rice, the *OsIAA11* gene was reported to play an essential role in the development of the root system (*Zhu et al., 2012; Ni et al., 2014*). According to the phylogenetic tree analysis, the homologous gene of *OsIAA11* in the apple was *MdIAA21*, which was preferentially expressed in flowers. This suggested that the *MdIAA* genes might not perform the same biological functions as the *IAA* genes in other already reported species.

As an important primary auxin-responsive gene family, auxin treatment rapidly induces the expression of the *IAA* family. According to the results of the *IAA* treatment, 17 apple *IAA* genes were selected and their expression patterns were studied. The expression of *MdIAA* genes was either higher or lower than the control after different amounts of exposure to *IAA* treatment. We concluded that the treatment time of *IAA* played a crucial role in the up-regulation or down-regulation of auxin responsive genes.

Extensive studies have shown that the changes in auxin concentration, redistribution, and signal transmission are affected by various integrated environmental factors (*Shibasaki et al., 2009*). Mounting evidence shows that the auxin-response genes, including *Aux/IAA*, *GH3*, and *SAUR* are related to stress and defense responses in *Arabidopsis*, maize, rice, and *Sorghum bicolor* (*Ghanashyam & Jain, 2009; Jain & Khurana, 2009*;

*Zhang et al., 2009; Wang et al., 2010a*). In our research, *MdIAAs* showed various expression patterns under different stress conditions. The expression levels of some *MdIAAs* increased after drought, cold, salt, and ABA exposure. However, the expression levels of some *MdIAAs* decreased after treatments. Similar results have been shown in other species. In the tomato, the up-regulated expression of most *SlIAAs* under drought and salt stress treatments was observed, while the expression levels of *SlIAA3*, *SlIAA11*, and *SlIAA14* decreased after stress treatments (*Wu et al., 2012*). Here, drought-inducibility elements (MBS), LTR motifs, and defense and stress responsiveness elements (TC-rich repeats) were shown to be upstream of the promoter regions in some *MdIAAs*. These cis-elements related to abiotic stress and auxin signaling regulating pathways might result in different expression patterns of *MdIAA* genes. However, the results from qRT-PCR analysis were inconsistent with the analysis of the promoter region on *MdIAA* genes. For instance, although some LTR motifs were found in *MdIAA24* and *MdIAA33*, no significant alterations in their expression levels were observed under the cold conditions and conversely, in the promoter regions of *MdIAA10* and *MdIAA20*, no cis-elements related to salt stress were found. However, qRT-PCR analysis showed that the two genes in question were significantly responsive to stress. This indicated that the expression of those *MdIAAs* in stress response might be regulated by some unidentified cis-regulated elements in the apple.

In the present study, as compared with the wild type, the OE of *MdIAA9* in tobacco seedlings increased their root lengths and fresh weights. Furthermore, this OE also induced a series of changes in tobacco seedlings related to abiotic stress responses, including REL, total chlorophyll concentration, free proline, and MDA content. The lower levels of REL and MDA and increased levels of proline and total chlorophyll in the overexpressed lines indicated that *MdIAA9* has a significant role in enhancing resistance to osmotic stress. The present study indicated that OE of *MdIAA9* in tobacco seedlings led to an enhancement of drought resistance.

## CONCLUSIONS

A total of 34 *MdIAA* genes were identified and characterized in this study. A comprehensive *MdIAA* gene family genome-wide analysis was presented, which included the phylogeny, chromosome locations, gene structures, and conserved motifs. Our research shows that most members of the *MdIAA* gene family have different patterns of spatio-temporal transcript accumulation. Exogenous auxin can induce *MdIAAs* at the transcriptional level, most of which may be induced by exposure to drought stress, salt, cold, and ABA in the apple. Our research also shows that the OE of *MdIAA9* in tobacco seedlings leads to an enhanced drought resistance. The comprehensive information from the results enhances our recognition of how *MdIAA* genes function at different points in the life cycle and under various abiotic stresses. Notably, the present study implies that the stress-responsive genes may be appropriate candidates to create stress-tolerant apple rootstocks and cultivars using transgenic technology.

## ADDITIONAL INFORMATION AND DECLARATIONS

### Funding

This work was supported by the earmarked fund for the China Agriculture Research System (CARS-27) and Tang Scholar. The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

### Grant Disclosures

The following grant information was disclosed by the authors:  
China Agriculture Research System (CARS-27) and Tang Scholar.

### Competing Interests

The authors declare that they have no competing interests.

### Author Contributions

- Dong Huang conceived and designed the experiments, authored or reviewed drafts of the paper, approved the final draft.
- Qian Wang performed the experiments, prepared figures and/or tables, approved the final draft.
- Dingyue Duan performed the experiments, contributed reagents/materials/analysis tools, prepared figures and/or tables, approved the final draft.
- Qinglong Dong conceived and designed the experiments, contributed reagents/materials/analysis tools, authored or reviewed drafts of the paper, approved the final draft.
- Shuang Zhao analyzed the data, contributed reagents/materials/analysis tools, approved the final draft.
- Maoxue Zhang analyzed the data, authored or reviewed drafts of the paper, approved the final draft.
- Guangquan Jing performed the experiments, prepared figures and/or tables, authored or reviewed drafts of the paper, approved the final draft.
- Changhai Liu analyzed the data, prepared figures and/or tables, authored or reviewed drafts of the paper, approved the final draft.
