As part of our studies on the synthesis and the characterization of oxalatebridged compounds M-ox-M (ox = oxalate dianion and M = transition metal ion), we report the crystal structure of a new oxalate-bridged Mn<sup>II</sup> phase, {(CH<sub>6</sub>N<sub>3</sub>)[Mn(C<sub>2</sub>O<sub>4</sub>)Cl(H<sub>2</sub>O)]·H<sub>2</sub>O}<sub>n</sub>. In the compound, a succession of Mn<sup>II</sup> ions (situated on inversion centers) adopting a distorted octahedral coordination and bridged by oxalate ligands forms parallel zigzag chains running along the *c* axis. These chains are interconnected through O–H···O hydrogenbonding interactions to form anionic layers parallel to (010). Individual layers are held together *via* strong hydrogen bonds involving the guanidinium cations (N–H···O and N–H···Cl) and the disordered non-coordinating water molecule (O–H···O and O–H···Cl), as well as by guanidinium  $\pi$ - $\pi$  stacking. The structural data were confirmed by IR and UV–Visible spectroscopic analysis.

### 1. Chemical context

Much attention had been devoted to the coordination chemistry of oxalate (ox) anions due to the interesting structural features and physical properties they possess (Chérif et al., 2011; Dridi et al., 2013; Decurtins et al., 1997). Oxalate anions have been demonstrated to be one of the most versatile bridging ligands for the construction of coordination polymers when combined with transition metal cations. Manganese(II) is a promising cation with possibilities of forming onedimensional oxalato-based coordination polymers, as evidenced by reports describing the structures of several topologically similar Mn<sup>II</sup>-ox-Mn<sup>II</sup> chains [see, for example, García-Couceiro et al. (2005) or Beznischenko et al. (2009)]. In those compounds, the oxalate-bridged manganese framework may be considered as a single-chain magnet based on the oxalate linker (e.g. Clemente-León et al., 2011). In this work, we report the synthesis and crystal structure determination of a new oxalate-bridged coordination compound,  $\{(CH_6N_3)[Mn(C_2O_4)Cl(H_2O)] \cdot H_2O\}_n$  (I).

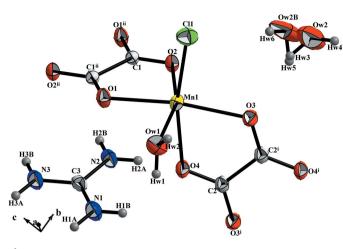

Figure 1

The structural unit of (I), showing the atom-numbering scheme. Displacement ellipsoids are drawn at the 50% probability level for non-H atoms. [Symmetry codes: (i) -x + 1, -y + 1, -z + 1; (ii) -x + 1, -y + 1, -z.]

#### 2. Structural commentary

The principal structural motifs of the title compound are the complex anion  $[MnCl(C_2O_4)(H_2O)]^-$ , the organic cation  $(CH_6N_3)^+$  and one disordered non-coordinating water molecule. A bond-valence-sum calculation, assuming Mn–O and Mn–Cl bonds, gives a BVS value (Brown & Altermatt, 1985) of 2.05 (7), confirming the +II oxidation state of Mn and ensuring electrical neutrality of the formed unit. The coordination environment of the Mn<sup>II</sup> ion involves two oxalate ligands exhibiting bis-chelating coordination modes, one chloride atom and one oxygen atom of the aqua ligand (Fig. 1) in a slightly distorted octahedral geometry. The small bite angles of the bis-chelating oxalate groups [73.99 (6)° for O3–Mn1–O4 and 75.35 (7)° for O1–Mn1–O2] and the extended Mn1–Cl1 bond [2.458 (2) Å] account for this distortion. The

# research communications

polyhedral distance and angle distortions, calculated from the Mn-O and Mn-Cl distances and O-Mn-O and O-Mn-Cl angles in the MnO<sub>5</sub>Cl unit, were found to be ID<sub>d</sub> = 0.03 (2) and ID<sub>a</sub> = 0.22 (4)%, respectively (Baur, 1974; Wildner, 1992).

The equatorial plane of the MnO<sub>5</sub>Cl octahedron is formed by atoms Mn1, OW1, O1, O2 and O3, with a calculated rootmean-square deviation of the fitted atoms of 0.1038 Å. The axial positions are occupied by the chloride atom [Mn1–Cl1 = 2.458 (2) Å] and one oxygen atom from the bridging oxalato group [Mn1–O4 = 2.248 (2) Å]. The two oxalato groups are almost perpendicular with a dihedral angle of 89.09 (6)°. The oxalate ion is located on an inversion center that also relates the two Mn atoms bonded to the oxalate ion with each other. The bridged metal ions are nearly coplanar with the oxalate plane with a mean deviation of 0.0147 (8) Å.

The Mn<sup>II</sup> ion, as a  $d^5$  high-spin system with a spherical electron distribution, has a limited number of commonly observed coordination geometries that are based on minimization of ligand–ligand repulsion. Among the Mn–O distances, the shortest are those involving an oxygen atom from the oxalate ion *trans* to another oxygen atom from the second oxalate ion. The range of these distances is 2.180 (1) to 2.194 (1) Å, which is in accord with those observed in other oxalate-bridged compounds such as one of the polymorphs of *catena*-poly[[diaquamanganese(II)]- $\mu$ -oxalato- $\kappa^4 O^1, O^2: O^{1'}, O^{2'}$ ] (Soleimannejad *et al.*, 2007). The Mn–O distances involving the oxygen atoms of the oxalate ion *trans* to the chloride atom are slightly longer at 2.202 (2) and 2.248 (2) Å.

The view of the structure packing (Fig. 2) shows the layered structure based on anionic zigzag oxalate-bridged  $Mn^{II}$  chains running along the *c* axis. The intra-chain  $Mn \cdots Mn$  distances through bridging oxalate are 5.695 (2) and 5.778 (2) Å, somewhat longer than the value of 5.652 Å previously observed for {[ $Mn(C_2O_4)(C_8H_7N_3)$ ]·1.5H<sub>2</sub>O}<sub>n</sub> (An & Zhu, 2009) involving a pyridyl-pyrazolide ligand instead of chloride

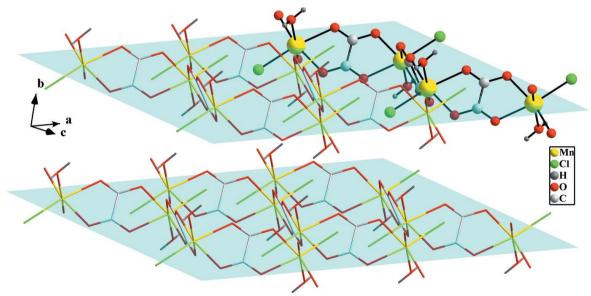

Figure 2 View of the structure packing showing Mn–Ox–Mn chains (highlighted by a ball-and-stick model) and layers parallel to (010) (blue planes).

# research communications

and aqua ligands in the coordination environment of the  $Mn^{II}$  ion.

The geometric parameters for the guanidinium cations do not show any unusual features and are in agreement with those previously reported (Sakai *et al.* 2003; Vaidhyanathan *et al.*, 2001). The bond lengths [1.318 (2)–1.329 (2) Å] and angles [119.27 (16)–120.57 (16)°] are in the typical ranges, confirming a highly resonance-stabilized electronic structure and a completely delocalized charge between the three  $sp^2$  nitrogen atoms. Conjugation of the nitrogen lone pairs with the empty *p*-orbital of the  $sp^2$  carbon atom creates a planar cation.

### 3. Supramolecular features

Neighbouring oxalate-bridged zigzag chains are connected with each other via  $O-H \cdots O$  hydrogen bonds involving the coordinating water molecule. Its oxygen atom acts as a hydrogen-bond donor and establishes strong hydrogen bonds (Table 1) towards one of the oxalate oxygen atoms of a neighbouring chain (Fig. 3),  $OW1-HW2\cdots O3^{\vee}$  [symmetry code: (v) -x + 2, -y + 1, -z], leading to the formation of anionic layers parallel to (010). A disordered non-coordinating water molecule acts as acceptor (Fig. 3) for the other hydrogen atom involving the coordinating water molecule via the hydrogen bonds  $OW1-HW1\cdots OW2^{i}$  and OW1- $HW1\cdots OW2B^{i}$  [symmetry code: (i) x, y - 1, z]. Both disorder components of the non-coordinating water molecules act as

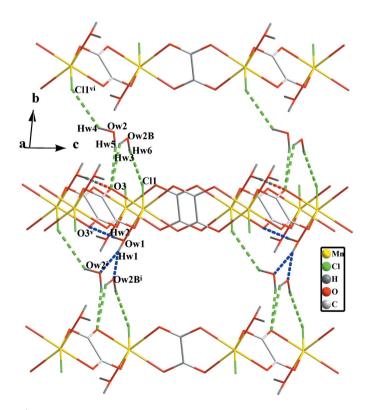

Figure 3

View of the hydrogen bonds developed by both coordinating (blue dashed lines) and non-coordinating (green dashed lines) water molecules. [Symmetry codes: (i) x, y - 1, z; (v) -x + 2, -y + 1, -z; (vi) -x + 2, -y + 2, -z.]

OW2−HW4···Cl1 <sup>vi</sup>	0.85(1)	2.61 (3)	3.319 (6)	142 (4)
$OW2B - HW5 \cdots O3$	0.85(1)	2.42 (11)	2.840 (10)	112 (9)
$OW2B - HW6 \cdots Cl1$	0.86(1)	2.81 (1)	3.656 (18)	172 (11)

Symmetry codes: (i) x, y - 1, z; (ii) x - 1, y, z; (iii) -x + 1, -y + 1, -z + 1; (iv) -x + 1, -y, -z + 1; (v) -x + 2, -y + 1, -z; (vi) -x + 2, -y + 2, -z.

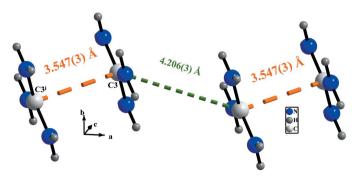

hydrogen-bond donors towards oxygen atom O3 (Fig. 3) *via* the hydrogen bonds  $OW2-HW3\cdots O3$  and OW2B- $HW5\cdots O3$ , but they form different hydrogen bonds *via* their second H atom, to chlorine atoms in different lattice positions *via* hydrogen bonds  $OW2-HW4\cdots Cl1^{vi}$  and OW2B- $HW6\cdots Cl1$  [symmetry code: (vi) -x + 2, -y + 2, -z]. The combined water hydrogen bonds link the anionic layers into a 3D framework.

The three N atoms of the guanidinium cation act as donors of hydrogen bonds N1-H1A···O2<sup>i</sup>, N1-H1B···O4, N2-H2A···Cl1<sup>ii</sup>, N2-H2B···Cl1<sup>iii</sup>, N2-H2A···O4, N3-H3A···O1<sup>iv</sup> and N3-H3B···Cl1<sup>iii</sup> [Table 1; symmetry codes: (i) x, y - 1, z; (ii) x - 1, y, z; (iii) -x + 1, -y + 1, -z + 1; (iv) -x + 1, -y, -z + 1], consolidating the anionic layers and giving additional stability to the three-dimensional structure as illustrated in Fig. 4. The guanidinium cations are also paired

N−H···O and N−H···Cl hydrogen-bonding interactions developed by the guanidinium cations (dashed lines) in (I). Non-coordinating water molecules and hydrogen atoms of coordinating water molecules are omitted for clarity. [Symmetry codes: (i) x, y - 1, z; (ii) x - 1, y, z; (iii) -x + 1, -y + 1, -z + 1; (iv) -x + 1, -y, -z + 1.]

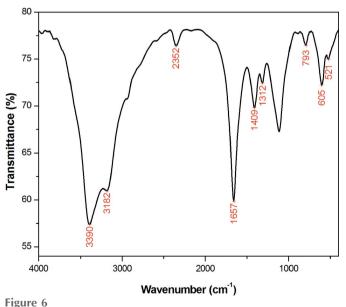

**Figure 5**  $\pi$ - $\pi$  stacking interactions (orange dashed lines) between adjacent organic cations. [Symmetry code: (i) -x, -y, -z + 1.]

*via*  $\pi$ - $\pi$  stacking with an interplanar distance of 3.547 (3) Å between C3 and C3(-x, -y, -z + 1) (Di Tondo & Pritchard, 2012), as shown in Fig. 5.

### 4. IR and UV-Vis characterizations

The IR spectrum was recorded in the 4000–400 cm<sup>-1</sup> region using a Perkin–Elmer spectrometer with the sample diluted in a pressed KBr pellet. The most intense IR absorption bands of (I) are given in Table 2. The spectrum (Fig. 6) displays broad and strong bands centered at 3390 and 3182 cm<sup>-1</sup> assigned to  $[\nu(O-H) + \nu_{as}(NH_2)]$  and  $\nu_s(NH_2)$ , respectively (Sasikala *et al.*, 2015). The broadness of these bands is indicative of the presence of both coordinating and non-coordinating water molecules, as well as  $-NH_2$  groups involved in an extensive hydrogen-bond framework, in agreement with the crystal structure. A weak band observed at 2352 cm<sup>-1</sup> is attributed to an N–H···O stretching mode. The characteristic vibrations of the bridging oxalato ligand are observed at 1657 cm<sup>-1</sup>  $[\nu_{as}(COO)]$ , 1312 and 1409 cm<sup>-1</sup>  $[\nu_s(COO)]$  and 793 cm<sup>-1</sup>  $[\delta(COO)]$  (Ma *et al.*, 2007). All these bands are consistent with

The IR spectrum of (I) in KBr.

Table 2IR data  $(cm^{-1})$  for (I).

Wavenumber	Assignment
521	$\nu(Mn-Cl)$
605	$\nu(Mn-O)$
793	δ(COO)
1312, 1409	$v_{s}(COO)$
1657	$v_{as}(COO)$
2352	$\nu(N-H\cdot\cdot O)$
3182	$\nu_{\rm s}(\rm NH_2)$
3390	$\nu(OH)(H_2O) / \nu_{as}(NH_2)$

Table 3

UV–Vis data (nm) for (I).

Wavelength	Assignment
206	$\pi { ightarrow} \pi^*$
240	MLCT
329	$n \rightarrow \pi^*$

the literature for a bis-chelating coordination of the oxalato ligand. Additional bands observed at around 605 and 521 cm<sup>-1</sup> can be attributed to  $\nu$ (Mn–Cl) (Zgolli *et al.*, 2011) and  $\nu$ (Mn–O) (Biradar & Mruthyunjayaswamy, 2013), respectively.

Some crystals, selected under the microscope, were dissolved in 10 cm<sup>3</sup> of distilled water. The solution obtained was analyzed using a UV–Visible spectrometer. The spectrum of (I) (Table 3 and Fig. 7) shows significant transitions at 206 nm (with a shoulder at 240 nm) and 329 nm. The first band is due to the  $\pi \rightarrow \pi^*$  transition of the guanidinium  $\pi$  system (Hoffmann *et al.*, 2009), the second witnesses the metal-to-ligand charge-transfer (Sun *et al.*, 1996) and the last corresponds to the  $n \rightarrow \pi^*$  transition (Sasikala *et al.*, 2015). An examination of the visible region of the spectrum does not reveal obvious d-d transitions (insert of Fig. 7) which may be

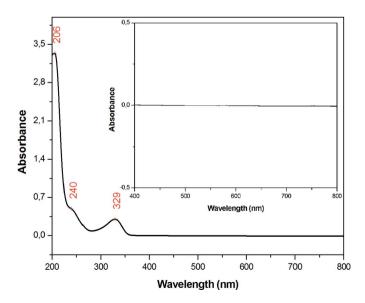

Figure 7 The UV–Vis spectrum of (I) in water. The insert is an expansion of the visible region.

too weak to be seen, as they are spin and Laporte forbidden, in accordance with the compound being almost colourless.

### 5. Synthesis and crystallization

Aqueous solutions of ammonium oxalate and guanidine hydrochloride were added to  $Mn(SO_4) \cdot H_2O$  dissolved in 10 cm<sup>3</sup> of water in a 1:2:1 molar ratio. The resulting solution was left at room temperature and colourless crystals suitable for X-ray diffraction were obtained after two weeks of slow evaporation.

### 6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 4.

Guanidinium hydrogen atoms were positioned geometrically as riding atoms (N-H = 0.86 Å) using adequate HFIX instructions and refined with AFIX instructions. Hydrogen atoms of the coordinating water molecule were found in Fourier difference maps. O-H distances were restrained to a value of 0.85 (1) Å and H···H distances were restrained to a value of 1.387 (1) Å.

The oxygen atom of the non-coordinating water molecule had unusually high displacement parameters, and was refined as disordered over two alternative mutually exclusive positions. The solvent molecule may be considered as being located vertically between negative-charged anionic layers formed by hydrogen-bonded polymeric chains and located horizontally between positive-charged pairs of guanidinium cations. This pseudo-channel affects its hydrogen-bonding interactions, see the discussion in the first paragraph of the *Supramolecular features* section and Fig. 3, which may explain the observed disorder.

The disordered oxygen atom was refined as disordered over two positions OW2 and OW2B which were restrained to have similar geometries. Their hydrogen atoms were located from the Fourier difference maps. The O-H bond lengths were restrained to a value of 0.85 (1) Å and the H···H distances were restrained to a value of 1.387 (1) Å. The interatomic distances between the two pairs OW2 and HW5 and OW2B and HW3 were restrained to be equal using a SADI instruction with an effective standard deviation of 0.02. The hydrogen-bonding distance of hydrogen atom HW6 to chlorine atom Cl1 was restrained to 2.80 (1) Å. Subject to these and the above conditions, the occupancy ratio of the disordered non-coordinating water molecule refined to 0.816 (13):0.184 (13).

## Refinement

Refinement on  $F^2$ Least-squares matrix: full  $R[F^2 > 2\sigma(F^2)] = 0.024$  $wR(F^2) = 0.065$ S = 1.102114 reflections Z = 2 F(000) = 278  $D_x = 1.884 \text{ Mg m}^{-3}$ Mo Ka radiation,  $\lambda = 0.71073 \text{ Å}$ Cell parameters from 25 reflections  $\theta = 10-15^{\circ}$   $\mu = 1.65 \text{ mm}^{-1}$  T = 298 KPrism, colourless  $0.50 \times 0.43 \times 0.34 \text{ mm}$ 

2018 reflections with  $I > 2\sigma(I)$   $R_{int} = 0.016$   $\theta_{max} = 27.0^{\circ}, \ \theta_{min} = 2.1^{\circ}$   $h = -8 \rightarrow 8$   $k = -9 \rightarrow 9$   $l = -12 \rightarrow 12$ 2 standard reflections every 120 reflections intensity decay: 1.4%

155 parameters11 restraintsPrimary atom site location: structure-invariant direct methodsSecondary atom site location: difference Fourier map

Hydrogen site location: inferred from neighbouring sites	$w = 1/[\sigma^2(F_o^2) + (0.034P)^2 + 0.1929P]$ where $P = (F_o^2 + 2F_c^2)/3$
H-atom parameters not refined	$(\Delta/\sigma)_{\rm max} = 0.001$
	$\Delta  ho_{ m max} = 0.39 \  m e \  m \AA^{-3}$
	$\Delta \rho_{\rm min} = -0.30 \text{ e} \text{ Å}^{-3}$

### Special details

**Geometry**. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

**Refinement**. Refinement of  $F^2$  against ALL reflections. The weighted R-factor wR and goodness of fit S are based on  $F^2$ , conventional R-factors R are based on F, with F set to zero for negative  $F^2$ . The threshold expression of  $F^2 > 2$ sigma( $F^2$ ) is used only for calculating R-factors(gt) etc. and is not relevant to the choice of reflections for refinement. R-factors based on  $F^2$  are statistically about twice as large as those based on F, and R- factors based on ALL data will be even larger.
