ABSTRACT *Salmonella enterica* (non-Typhi) is one of the top five pathogens causing enteric infections worldwide. Draft whole-genome sequences of multidrug-resistant (MDR) *Salmonella enterica* serovar I 4,[5],12:i:– isolates from swine tissue samples collected at slaughter were evaluated for antimicrobial resistance genotypes. In recent years, *Salmonella enterica* serovar I 4,[5],12:i:– has increased in prevalence in humans and animals and has been linked to the consumption of contaminated pork.

Salmonella enterica (non-Typhi) is one of the most common foodborne pathogens and is the causative agent of salmonellosis in humans. There are nearly 1.2 million illnesses and 450 deaths related to *Salmonella* infections every year in the United States (1, 2). Common gastrointestinal symptoms that develop with salmonellosis in humans are diarrhea, abdominal pain, and fever (3). However, serious infections can lead to hospitalization or death, particularly in young children, adults over 65 years old, and those who are immunocompromised.

There are a limited number of *Salmonella* serovars that are responsible for the majority of cases of human salmonellosis (4). In particular, multidrug-resistant (MDR) *Salmonella enterica* serovar I 4,[5],12:i:– has been on the rise in both humans and animals, as reported by the National Antimicrobial Resistance Monitoring System (NARMS) (5). An increasing prevalence of antimicrobial resistance has been observed in nontyphoidal *Salmonella* over recent decades (3, 6). The recent rise in MDR nontyphoidal *Salmonella* infections is largely driven by the increase in *Salmonella enterica* serovar I 4,[5],12:i:– with resistance to ampicillin, streptomycin, sulfonamide, and tetracycline (ASSuT) (7). The isolates described here are *Salmonella enterica* serovar I 4,[5],12:i:– isolates cultured by the United States Department of Agriculture Agricultural Research Services (USDA ARS, College Station, TX) from swine tissue samples collected at slaughter.

Salmonella enterica serovar I 4,[5],12:i:– isolates were cultured using standard culture and enrichment techniques from swine head trim and cheek meat samples (8). Samples were collected every other month from January to November 2015 from a pork processing plant in the United States and shipped to the USDA ARS (College Station, TX). Previously cultured isolates were streaked onto tryptic soy agar with 5% sheep blood and incubated at 37°C for 18 hours (Remel, Lenexa, KS). A single colony was selected and inoculated into 5 ml of tryptic soy broth for DNA extraction. DNA isolation was performed using QIAmp 96 DNA QIAcube HT kits and the QIAcube HT instrument (Qiagen, Valencia, CA) (9). DNA quality and quantity were verified by DNA absorbance and fluorescence using the FLUOstar Omega plate reader (BMG Labtech,

Cary, NC). Whole-genome sequencing libraries were prepared using Nextera XT library preparation kits (Illumina, San Diego, CA) with a fragment length of 600 bp and sequenced on the Illumina MiSeq platform using MiSeq reagent kits v3 with 2 × 300-bp paired-end reads. Default parameters were used for all bioinformatics software unless otherwise specified. FastQC v0.11.07 was used to assess the quality of the raw Illumina reads and determine the total number of reads generated (10). Trimmomatic v0.36 was used to remove adapter/primer sequences, low-quality bases, and reads with a quality threshold of 3 for reading and trailing, using the following parameters: 4:15 SLIDING-WINDOW, minimum length of 36 bases, and a Phred quality score of 33 (11). The genomes were assembled using the *de novo* assembler SPAdes v3.5 (12), and the quality of assembly was evaluated using QUAST (v4.6) (13). Resistance genes were found using the raw sequencing data in ResFinder (v3.0) (14). The National Center for Biotechnology Information (NCBI) Prokaryotic Genome Annotation Pipeline (PGAP) was

used to annotate the genomes (15). Phenotypic antimicrobial susceptibility patterns of *Salmonella enterica* serovar I 4,[5],12:i:– isolates were identified by broth microdilution on a Sensititre system (Trek, Thermo Scientific Microbiology, Oakwood Village, OH), using Gram-negative National Antimicrobial Resistance Monitoring System (NARMS) CMV3AGNF plates, and defined as susceptible, intermediate, or resistant, according to Clinical and Laboratory Standards Institute (CLSI) MIC breakpoints or to NARMS breakpoints when CLSI criteria are not established.

A total of 45 out of 47 *Salmonella enterica* serovar I 4,[5],12:i:– isolates sequenced were found to be phenotypically MDR, defined as resistant to 3 or more antibiotic classes. Forty isolates were found to harbor *bla*_{TEM-1}, *strA*, *strB*, *sul2*, and *tet(B)*, commonly known as the ampicillin, streptomycin, sulfonamide, and tetracycline resistance type (R-type ASSuT). We found that 32 isolates with the R-type ASSuT also contained the plasmid-mediated quinolone resistance (PMQR) gene *qnrB*. Three isolates harbored additional resistance genes to streptomycin-spectinomycin (*aadA2*), aminoglycosides [*aph(3')-I*], sulfonamides (*sul1*), beta-lactams (*bla*_{SHV-12}), and tetracyclines [*tet(D)*]. Future comparative analyses will advance our understanding of genome evolution and multidrug resistance in *Salmonella enterica* serovar I 4,[5],12:i:–.

Data availability. This whole-genome shotgun sequencing project has been deposited in DDBJ/EMBL/GenBank under the accession numbers shown in Table 1. The raw sequencing reads have been submitted to the SRA database under the accession number [SRP139298](#), and the BioProject accession number is [PRJNA449363](#). The versions described in this paper are the first versions.

ACKNOWLEDGMENTS

This work utilized the computational resources of the NIH HPC Biowulf cluster (<http://hpc.nih.gov>).
