ABSTRACT

Emerging evidence has shown that resting quiescent hematopoietic stem cells (HSCs) prefer to utilize anaerobic glycolysis rather than mitochondrial respiration for energy production. Compelling evidence has also revealed that altered metabolic energetics in HSCs underlies the onset of certain blood diseases; however, the mechanisms responsible for energetic reprogramming remain elusive. We recently found that Fanconi anemia (FA) HSCs in their resting state are more dependent on mitochondrial respiration for energy metabolism than on glycolysis. In the present study, we investigated the role of deficient glycolysis in FA HSC maintenance. We observed significantly reduced glucose consumption, lactate production, and ATP production in HSCs but not in the less primitive multipotent progenitors or restricted hematopoietic progenitors of *Fancc*^{-/-} and *Fancc*^{-/-} mice compared with that of wild-type mice, which was associated with an overactivated p53 and TP53-induced glycolysis regulator, the TIGAR-mediated metabolic axis. We utilized *Fancc*^{-/-} HSCs deficient for p53 to show that the p53-TIGAR axis suppressed glycolysis in FA HSCs, leading to enhanced pentose phosphate pathway and cellular antioxidant function and, consequently, reduced DNA damage and attenuated HSC exhaustion. Furthermore, by using *Fancc*^{-/-} HSCs carrying the separation-of-function mutant *p53*^{R172P} transgene that selectively impairs the p53 function in apoptosis but not cell-cycle control, we demonstrated that the cell-cycle function of p53 was not required for glycolytic suppression in FA HSCs. Finally, ectopic expression of the glycolytic rate-limiting enzyme PFKFB3 specifically antagonized p53-TIGAR-mediated metabolic reprogramming in FA HSCs. Together, our results suggest that p53-TIGAR metabolic axis-mediated glycolytic suppression may play a compensatory role in attenuating DNA damage and proliferative exhaustion in FA HSCs. *STEM CELLS* 2019;37:937–947

SIGNIFICANCE STATEMENT

This study shows that Fanconi anemia (FA) hematopoietic stem cells (HSCs), but not less primitive multipotent progenitors, exhibit significantly lower glycolysis than that in wild-type HSCs, which is associated with an overactivated p53-TP53-induced glycolysis regulator (TIGAR) metabolic axis. Furthermore, the p53-TIGAR axis suppresses glycolysis in FA HSCs, leading to enhanced pentose phosphate pathway and cellular antioxidant function, and consequently reduced DNA damage and HSC exhaustion. Ectopic expression of PFKFB3 specifically antagonizes p53-TIGAR-mediated metabolic reprogramming in FA HSCs. These results identify a compensatory role for the p53-TIGAR metabolic axis-mediated glycolytic suppression in attenuating DNA damage and genomic instability in FA HSCs.

INTRODUCTION

Fanconi anemia (FA) is a rare inherited disease characterized by bone marrow (BM) failure and high risk of neoplasia including leukemia from dysfunctional hematopoietic stem cells (HSCs; [1, 2]). FA is genetically heterogeneous with at least 22 genes (*FANCA-W*) identified thus far [1–11]. The hematologic complications of FA are nearly universal among patients with FA and defects in HSCs have been postulated as the root cause of BM

failure and leukemia in FA [6, 12]. Emerging evidence suggests that dysregulated energy metabolism is one possible mechanism underlying FA HSC defect. For example, compared with wild-type (WT) HSCs, FA HSCs are more dependent on oxidative phosphorylation (OXPHOS) relative to glycolysis for energy metabolism and undergo glycolysis-to-OXPHOS switch in response to oxidative stress through a p53-dependent mechanism [12]. However, how p53 regulates energy metabolism in FA HSCs is not well defined.

The role of p53 in tumor suppression is well known and loss of p53 function can lead to cancer [13, 14]. Although p53 mutations are common in solid tumors, such mutations are found at lower frequencies in hematologic malignancies [15, 16]. Recent studies have shown that p53 plays a crucial role in hematopoiesis by regulating HSC self-renewal and quiescence [17–20]. p53 is also a key regulator of cellular energy metabolism [21–23]. For example, p53 can inhibit glycolysis through transcriptional activation of its target gene TP53-induced glycolysis regulator (*TIGAR*; an inhibitor of the fructose-2,6-bisphosphate) [24]. However, since HSCs predominantly utilize glucose for energy metabolism, how p53 functions in glycolytic regulation in the context of HSC homeostasis is not known.

TIGAR shares functional sequence similarities with the bisphosphatase domain (FBPase-2) of the bi-functional enzyme phosphofructokinase (PFK)-2/FBPase-2 (6-phosphofructo-kinase/fructose-2,6-bisphosphatase), which degrades fructose-2,6-bisphosphate (Fru-2,6-BP; [25]). TIGAR causes a decline in Fru-2,6-BP levels in cells, resulting in glycolysis inhibition and an overall decrease in intracellular reactive oxygen species (ROS) and thus directing the pathway into the pentose phosphate shunt to produce NADPH [24, 26]. We propose that the p53-TIGAR axis may be responsible for the suppression of glycolysis in FA HSCs that we previously observed. In the present study, we have used the *Fanca*^{-/-}, *p53*^{-/-}, and *p53*^{-/-}*Fanca*^{-/-} knockout mouse models to show that p53-TIGAR-mediated glycolytic suppression attenuates ROS production, reduces DNA damage, ameliorates chromosomal instability, and consequently prevents premature exhaustion of FA HSCs. Our findings reveal a novel function of the p53-TIGAR metabolic axis in the maintenance of FA HSCs.

MATERIALS AND METHODS

Animals

Fanca^{+/-}, *Fanc*^{+/-}, and *p53*^{R172P} mice were generously provided by Dr. Madeleine Carreau (Laval University), Dr. Manuel Buchwald (Hospital for Sick Children, University of Toronto), and Dr. Guillermina Lozano (University of Texas M.D. Anderson Cancer Center), respectively [27–29]. *p53*^{-/-}*Fanca*^{-/-} and *p53*^{R172P}*Fanca*^{-/-} mice were generated by interbreeding the heterozygous *Fanca*^{+/-} with *p53*^{+/-} mice (C57BL/6: B6, CD45.2⁺; the Jackson Laboratory, Bar Harbor, ME; [30]) or heterozygous *Fanca*^{+/-} with *p53*^{R172P} mice. Eight- to 12-week-old animals were used for all the experiments. All the animals including BoyJ (C57BL/6: B6, CD45.1⁺) recipient mice were maintained in the animal facility at West Virginia University (WVU) Health Science Center. All experimental procedures conducted in this study were approved by the Institutional Animal Care and Use Committee of WVU.

Flow Analysis and Cell Sorting

Femurs and tibias were flushed to dissociate the BM fraction. Cells were resuspended in 5 ml of phosphate-buffered saline (PBS)/0.5% bovine serum albumen (BSA) and filtered through a 70- μ m filter (BD Biosciences, catalog no. 3523350, San Jose, CA). The mononuclear cells were isolated by Ficoll-Paque (GE Healthcare, catalog no. 95040-394, Pittsburgh, PA) gradient centrifugation. The following antibodies were used for flow cytometry analyses: APC-Cy7-anti-c-kit (BioLegend, catalog no. 105825, San Diego, CA), PE-Cy7-anti-Sca-1 (BD Biosciences, catalog

no. 105825), APC-anti-CD150 (BioLegend, catalog no. 115909), Pacific Blue-anti-CD48 (BioLegend, catalog no. 103417), and PE-anti-CD45.1, APC-anti-CD45.2 (both from BD Biosciences, catalog nos. 553776 and 558702). For Lineage⁻Sca-1⁺c-kit⁺ (LSK) staining, cells were incubated by the biotin conjugated antilineage antibody cocktail (BioLegend, catalog no. 133307) followed by staining with a secondary PerCP-Cy5.5 anti-Streptavidin antibody (BioLegend, catalog no. 405214), PE-Cy7-anti-Sca-1 antibody (BD Biosciences), and APC-Cy7-anti-c-kit antibody (BD Biosciences). To measure long-term HSC subpopulation, cells were stained with LSK antibodies in addition to CD150-APC and CD48-Pacific blue (both from BioLegend, catalog nos. 115909 and 103417). Flow cytometry was performed on LSRFortessa (BD Biosciences) and analysis was done with FCS Express 6 software (De Novo Software, Los Angeles, CA). For the cell sorting, lineage negative cells were enriched using lineage depletion reagents (Miltenyi Biotec, catalog no. 130-090-858, Auburn, CA) according to the manufacturer's instruction. The Lin⁺ or LSK (Lin⁻c-kit⁺Sca-1⁺) fractions were acquired by using the fluorescence-activated cell sorting (FACS) Aria II sorter (BD Biosciences).

To detect reactive oxygen species (ROS) level, surface marker stained cells were washed with PBS twice followed by incubation with H₂DCFDA working solution (10 μ M H₂DCFDA in prewarmed PBS; Molecular Probes, catalog no. D399, Eugene, OR) at 37°C for 15 minutes. H₂DCFDA intensity was analyzed by flow cytometry.

For cell-cycle analysis, surface marker stained cells were fixed and permeabilized using Cytofix/Cytoperm buffer (BD Pharmingen, catalog no. 554722, San Jose, CA) followed by intensive wash using Perm/Wash Buffer (BD Pharmingen, catalog no. 554723). Cells were then labeled with Pyronin Y staining buffer (150 ng/ml Pyronin Y in Perm/Wash buffer; Sigma-Aldrich, catalog no. 92-32-0, St. Louis, MO) at 37°C for 1 hour followed by flow cytometry analysis on CD45.2⁺ signaling lymphocyte activation molecule (SLAM) (Lin⁻Sca1⁺c-kit⁺CD150⁺CD48⁻) gated population.

For γ -H2AX staining, surface marker stained cells were fixed and permeabilized using Cytofix/Cytoperm buffer (BD Pharmingen, catalog no. 554722) followed by intensive wash using Perm/Wash Buffer (BD Pharmingen, catalog no. 554723). Cells were then blocked with 2% BSA/PBS for 20 minutes at room temperature in dark followed by incubation with primary anti- γ -H2AX antibody (biotin-conjugated, Millipore, catalog no. 16-193, Billerica, MA). After washing, cells were then incubated with secondary FITC-anti-streptavidin antibody (BD Pharmingen, catalog no. 554060) and analyzed by flow cytometry analysis.

For lineage differentiation, single-cell suspensions were incubated with various combination of the following cell-surface marker antibodies: CD45.2-FITC, Gr1-APC, Mac1-PE-Cy7, CD45.2-APC, CD3e (all from BD Pharmingen, catalog nos. 553772, 553129, 552850, 558702, and 553062), and B220-PE (eBioscience, catalog no. 12-0452-85). Immunolabeled cells were analyzed by flow cytometry.

Measurements of Glucose Consumption, Lactate Production, ATP, and PFK1 Activity

Glucose consumption, lactate production, and PFK activity were measured using the Glucose Assay Kit, the Lactate Assay Kit, and the Phosphofructokinase Activity Colorimetric Assay Kit (all from Biovision, catalog nos. K686, K607, and K776, Milpitas,

CA) according to the manufacturer's instructions, respectively. Intracellular adenosine triphosphate (ATP) levels and fructose-6-phosphate (F6P) levels were determined in cell lysates using the ATP Bioluminescent Somatic Cell Assay Kit and Fructose-6-Phosphate Assay Kit (Sigma–Aldrich, catalog nos. FLASC and MAK020) following the manufacturer's instructions.

Measurements of Fru-2,6-P₂ Level, NADPH/NADP⁺ Ratio, and Intracellular GSH Level

PBS-washed cells were lysed in NaOH/Tris acetate by heating at 80°C for 5 minutes. Lysates were neutralized to pH 7.2 by adding ice-cold acetic acid and HEPES (both from Sigma–Aldrich, catalog nos. A6283 and H3375). Fru-2,6-P₂ concentration was determined using the previously described method [31,32]. NADPH/NADP⁺ ratios were determined by using an enzyme-based colorimetric reaction kit (NADP⁺/NADPH Quantification Kit, BioVision, catalog no. K347-100, Milpitas, CA).

Intracellular reduced glutathione (GSH) levels were measured enzymatically with GSH reductase [33] using the BIOXYTECH GSH-400 Kit (Oxis Research, catalog no. 21011, Abingdon, Oxfordshire, U.K.) according to the manufacturers' instructions. Briefly, cells from the indicated mice were washed and lysed in 0.9 ml of 100 mM Tris–Cl by freeze-thaw cycling. Supernatants from the cells' suspension after centrifugation were transferred to Eppendorf tubes containing 0.1 ml of 30% 5-sulfosalicylic acid and incubated on ice for 15 minutes. Cell extracts were then centrifuged for 2 minutes at 12,000 rpm to get the supernatants. Protein concentration was assessed through the BioRad protein assay (Bio-Rad, catalog no. 5000002, Hercules, CA). GSH levels per 100 µl sample were then measured spectrophotometrically by conversion of 5,5'-dithio-bis (2-nitrobenzoic acid) to its colored product upon reduction by GSH-dependent GSH reductase and expressed as nmol GSH/mg protein.

Western Blotting

Thirty thousand LSK cells from indicated mice were washed with ice-cold PBS and lysed in an ice-cold lysis buffer containing 50 mM Tris–HCl (pH 7.4), 0.1% NP40, and 1 M NaCl supplemented with protease and phosphatase inhibitors (10 µg/ml of aprotinin, 25 µg/ml of leupeptin, 10 µg/ml of pepstatin A, 2 mM phenylmethylsulfonyl fluoride, 0.1 M NaP₂O₄, 25 mM NaF, and 2 mM sodium orthovanadate) for 30 minutes on ice. Cell debris was removed from the lysate by centrifugation. Protein lysate was resolved on SDS-PAGE and transferred onto nitrocellulose membranes. Immunoblots were then probed with primary antibodies for TIGAR (clone ab189164; Abcam, Cambridge, MA), total p53 (clone pAb240; Calbiochem), p53-S18 (clone ab1431; Abcam, Cambridge, MA), γ-H2AX (NB100-384, Novus, Littleton, CO), and β-actin (Sigma–Aldrich, catalog no. A5316) for 12–16 hours at 4°C. Signals were visualized by incubation with anti-mouse secondary antibody, followed by enhanced chemiluminescence (Amersham Biosciences, catalog no. RPN2106, Pittsburgh, PA).

Quantitative Polymerase Chain Reaction

Total RNA was extracted using RNeasy Kit (Qiagen, catalog no. 74104, Valencia, CA) following the manufacturer's procedure. Reverse transcription was carried out at 42°C for 60 minutes and stopped at 95°C for 5 minutes using random hexamers and Superscript II RT (Invitrogen, catalog no. 18064014, Grand Island, NY). First-strand cDNA was used for

real-time polymerase chain reaction (PCR) using primers listed in Supporting Information Table S1. Samples were normalized to the level of glyceraldehyde-3-phosphate dehydrogenase (*Gapdh*) mRNA.

Chromosomal Breakage Analysis

Chromosomal breakage analysis was performed on LSK cells from WT, *Fanca*^{-/-}, *p53*^{-/-}, and *p53*^{-/-}*Fanca*^{-/-} mice as previously described [34]. In brief, cells were treated with 0.05 mg/ml Colcemid (Invitrogen, catalog no. 15210-016) for 1.5 hours followed by 0.4% KCl hypotonic solution at 37°C for 20 minutes. Cells were then fixed with methanol and acetic acid (Sigma–Aldrich, catalog no. A6283) at 4°C for 15 minutes and dropped onto microscope slides. The cells were then rinsed with isoton stained with Giemsa for 5 minutes. The slides were then rinsed with Gurr Buffer (CTL Scientific, catalog no. 50-300-398, Deer Park, NY) and Milli-Q-filtered deionized water. Fifty cells from each sample were scored for chromosome aberrations.

Lentiviral Vector Construction, Virus Production, and Transduction

To generate lentiviral expression vectors for *TIGAR* and *PFKFB3*, the *TIGAR* cDNA was amplified from transomic plasmid OMu13565 and *PFKFB3* cDNA was amplified from transomic plasmid OMu19009 (both were from GenScript, Piscataway Township, NJ), respectively, and cloned into the pLVX-IRES-mCherry vector (Clontech, catalog no. 631237, Mountain View, CA).

Lentivirus was produced in 293 T cells after transfection of 20 µg plasmid, 15 µg pCMVΔ8.91 helper plasmid, and 6 µg pMD.G [35] using standard calcium phosphate transfection procedures. Fresh medium change was performed 12 hours after transfection. Supernatants from the cell-culture were collected 48 hours after transfection, filtered through 0.45 µm pore-size filters, and concentrated at 25,000 rpm for 2.5 hours at 4°C to harvest viral particles. Virus pellet was resuspended in sterile PBS and stored at –80°C.

For lentivirus transduction, the sorted LSK cells from WT, *p53*^{-/-}, *Fanca*^{-/-}, and *p53*^{-/-}*Fanca*^{-/-} were maintained in StemSpan Serum-Free Expansion Media (StemCell Technologies, catalog no. 09600, Vancouver, BC, Canada) supplemented with 50 ng/ml stem cell factor and 50 ng/ml thrombopoietin (both from Peprotech, catalog nos. 500-P71 and 315-14, Rocky Hill, NJ) for 24 hours before transduction. A multiplicity of infection of 5 were used for *TIGAR* or *PFKFB3* overexpression. After overnight transduction, cells were cultured in the presence of 0.5 mg/ml polybrene and refed with fresh medium the next day. Transduced cells were used in further assays at least 3–4 days after transduction.

BM Transplantation

For competitive repopulating units (CRUs), serial dilutions of LSK cells (CD45.2⁺) transduced with mCherry or mCherry-*TIGAR* lentivirus (25, 75, 150, and 250 mCherry⁺ cells) were mixed with 2 × 10⁵ protector BM cells from congenic mice (BoyJ) and injected into lethally irradiated (11.75 Gy) BoyJ mice (CD45.1⁺). The CRU frequencies were then calculated from the proportions of negative mice (<1% donor engraft). Poisson statistics at 8 weeks and 16 weeks post-transplantation was performed using the L-Calc software (StemCell Technologies).

For serial BM transplantation, 1,000 mCherry-sorted mCherry or mCherry-*TIGAR* lentiviral vector-transduced LSK cells

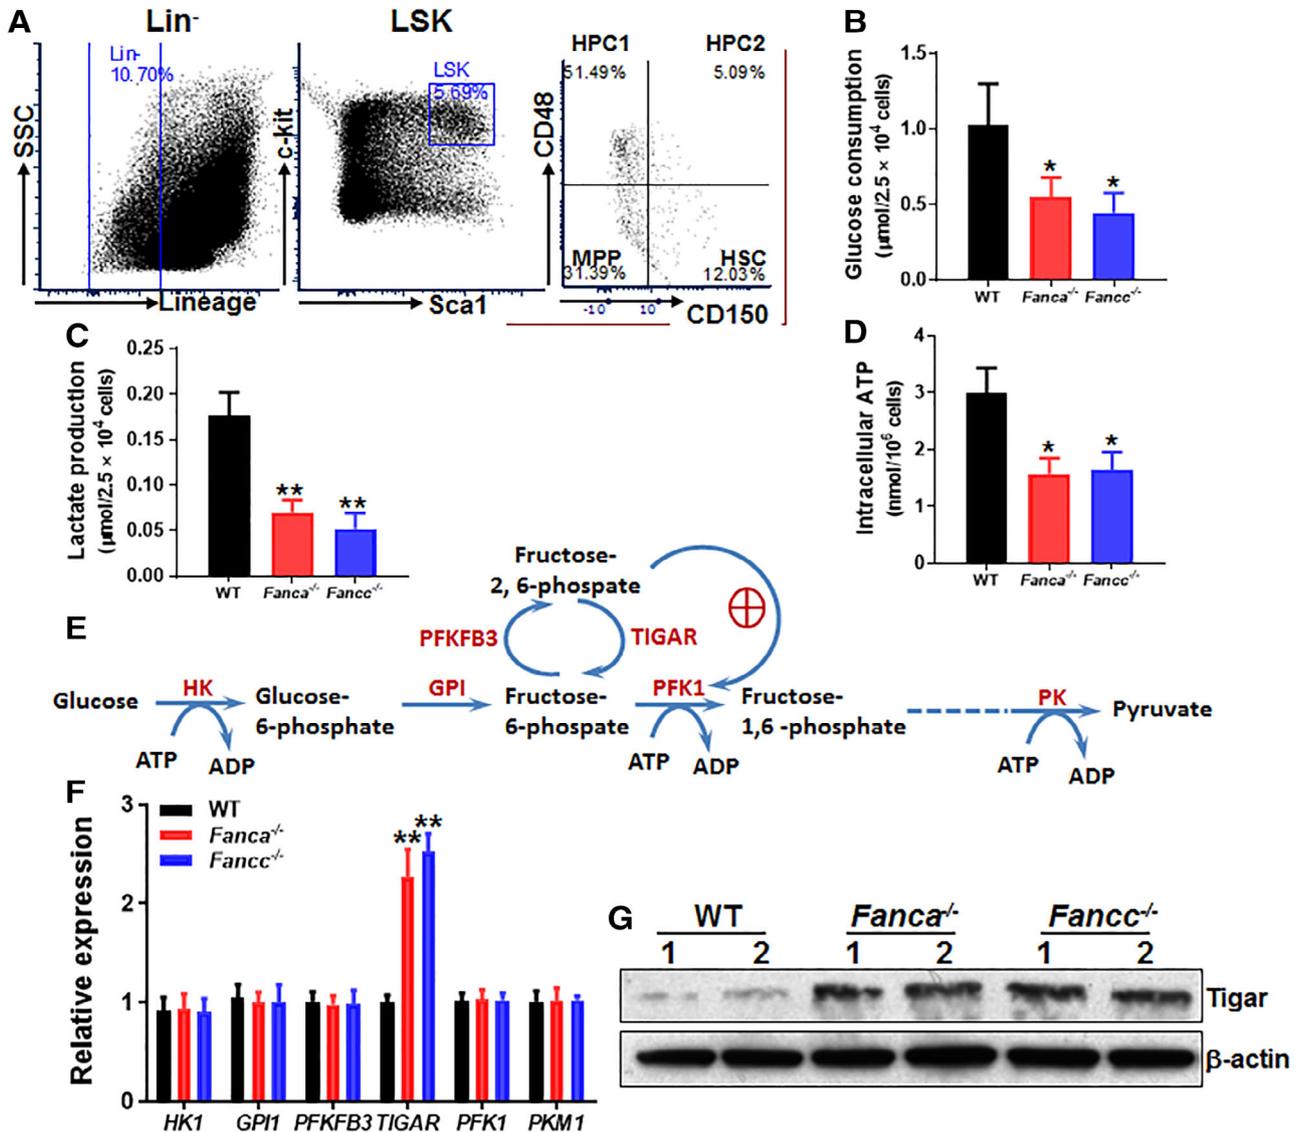

Figure 1. Reduced glycolysis in Fanconi anemia (FA) hematopoietic stem cells (HSCs). **(A):** Gating strategy for FACS sorting. **(B):** Reduced glucose consumption in FA HSCs. SLAM ($\text{Lin}^- \text{Sca-1}^+ \text{c-kit}^+ \text{CD150}^+ \text{CD48}^-$) cells from the bone marrow of $\text{Fanca}^{-/-}$, $\text{Fance}^{-/-}$, and wild-type (WT) mice were isolated by FACS sorting and subjected to analysis for glucose consumption analysis. **(C):** Reduced lactate production in FA HSCs. (CD45.2^+), mixed with 200,000 c-kit-depleted protector cells, were transplanted into lethally irradiated BoyJ mice. Sixteen weeks after BM transplantation, the recipients were subjected to flow cytometry analysis for donor-derived cells. For secondary BM transplantation, one million BM cells from the primary recipient mice were pooled and transplanted into sublethally irradiated (7.0 Gy) secondary CD45.1^+ recipient mice. Four months later, donor blood chimera was determined by staining peripheral blood (PB) samples with APC- CD45.2 (BD Biosciences, catalog no. 558702) and analyzed on a FACS canto instrument (BD Biosciences).

Statistics

Statistical analysis was done using a standard *t* test (Prism v6.0). The level of the statistical significance stated in the text was based on the *p* values. $p < .05$ was considered statistically significant.

RESULTS

FA HSCs Exhibit Reduced Glycolysis

To examine the role of glycolysis in FA HSC maintenance, we first compared glycolytic flux in different hematopoietic cell

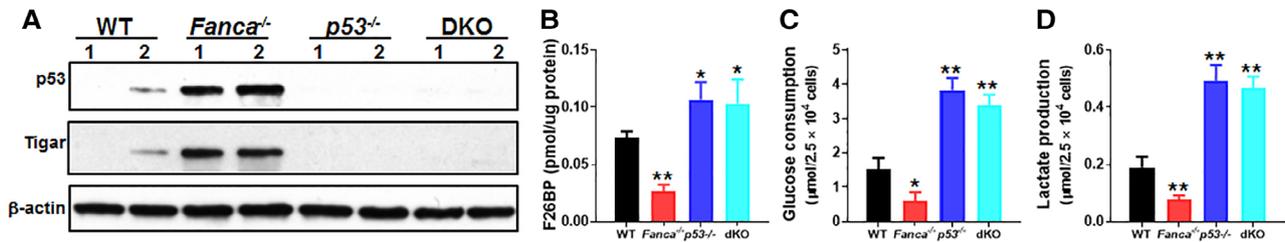

Figure 2. p53-Dependent suppression of glycolysis in Fanconi anemia (FA) hematopoietic stem cells (HSCs). **(A):** Increased p53 and TP53-induced glycolysis regulator (TIGAR) proteins in FA HSPCs. Whole-cell lysates were extracted from 30,000 Lineage⁻Sca-1⁺c-kit⁺ isolated from wild-type (WT), *Fanca*^{-/-}, *p53*^{-/-}, or *p53*^{-/-}*Fanca*^{-/-} mice followed by immunoblotting using antibodies against p53, TIGAR, or β-actin. **(B):** Deletion of *p53* increases F2,6BP level in *Fanca*^{-/-} HSCs. SLAM cells isolated from WT, *Fanca*^{-/-}, *p53*^{-/-}, or *p53*^{-/-}*Fanca*^{-/-} mice were subjected to MicroAssay for F26BP. **(C, D):** Deletion of *p53* increases glucose consumption and lactate production in FA HSCs. SLAM cells isolated from WT, *Fanca*^{-/-}, *p53*^{-/-}, or *p53*^{-/-}*Fanca*^{-/-} mice were subjected to glucose uptake (C) and lactate production analysis (D). compartments (Fig. 1A) of WT, *Fanca*^{-/-}, and *Fancc*^{-/-} mice. We found that glucose consumption rate in FA HSCs (Lin⁻Sca1⁺c-kit⁺CD150⁺CD48⁻) was significantly lower than those in WT HSCs (Fig. 1B), whereas the glucose usage in less primitive multipotential progenitors (MPPs; Lin⁻Sca1⁺c-kit⁺CD150⁻CD48⁻), restricted hematopoietic progenitor cells (HPCs; Lin⁻Sca1⁺c-kit⁺CD150⁻CD48⁺ and Lin⁻Sca1⁺c-kit⁺CD150⁺CD48⁺), and Lin⁺ cells were comparable among the three genotypes (Supporting Information Fig. S1A). Similar reduction was observed in lactate production (Fig. 1C) and intracellular ATP level (Fig. 1D) in FA HSCs in comparison to WT HSCs but not in MPPs, HPCs, or Lin⁺ cells from *Fanca*^{-/-} or *Fancc*^{-/-} mice (Supporting Information Fig. S1B, S1C).

It is known that glycolysis is tightly regulated by a series of enzymes and that crucial adjustments in glycolytic flux are set by the intracellular levels of fructose-2,6-bisphosphate (Fru-2,6-BP), which is controlled by a family of bifunctional enzymes, the 6-phosphofructo-2-kinase/fructose-2,6-bisphosphatases (PFKFB), including PFKFB3 and TIGAR [36, 37]. PFKFB3 has a much higher kinase activity than bisphosphatase activity, thus favoring the production of Fru-2,6-BP, whereas TIGAR functions as a fructose-2,6-bisphosphatase, thus decreasing the intracellular levels of Fru-2,6-BP (Fig. 1E). Thus, we measured the expression of the genes encoded for several key enzymes of the glycolysis pathway in WT and FA HSCs. Although there were no significant changes in the expression of *HK1*, *GPI1*, *PFKFB3*, *PFK1*, and *PKM1*, we observed a significantly (>twofold) increased expression of *TIGAR* in *Fanca*^{-/-} and *Fancc*^{-/-} HSCs compared with that in WT HSCs (Fig. 1F). In addition, TIGAR protein levels in FA HSCs were also found markedly increased in LSK cells from *Fanca*^{-/-} and *Fancc*^{-/-} mice (Fig. 1G). Accordingly, fructose-6-phosphate (F6P) was increased in FA hematopoietic stem progenitor cells (HSPCs) (Supporting Information Fig. S2). These results indicate a correlation between upregulated TIGAR and reduced glycolysis in FA HSCs.

p53-Dependent Suppression of Glycolysis in FA HSCs

Since p53 regulates glycolysis and since TIGAR is a p53 target, we then attempted to delete the p53 gene in *Fanca*^{-/-} mice and determined the role of p53-TIGAR axis in glycolytic suppression and HSC maintenance in FA. We first determined p53 levels in BM LSK cells from mice of four genotypes (WT, *Fanca*^{-/-}, *p53*^{-/-}, and *Fanca*^{-/-}*p53*^{-/-} double knockout [DKO]) produced from the *Fanca*^{+/-} × *p53*^{+/-} cross. The level of p53 protein in *Fanca*^{-/-} LSK cells was substantially higher than that in WT cells and no p53 was detected in *p53*^{-/-} and *Fanca*^{-/-}*p53*^{-/-} DKO HSPCs (Fig. 2A). Consistently, *Fanca*^{-/-} HSPCs showed increased

TIGAR compared with WT cells, which was not expressed in *p53*^{-/-} and *Fanca*^{-/-}*p53*^{-/-} DKO HSPCs (Fig. 2A) suggesting that the expression of TIGAR is dependent on p53.

Consistent with increased TIGAR expression, the levels of F-2,6-BP were significantly lower in *Fanca*^{-/-} HSCs but higher in *p53*^{-/-} HSCs compared with that in WT HSCs (Fig. 2B). Deletion of *p53* in *Fanca*^{-/-} HSCs also increased the levels of F-2,6-BP (Fig. 2B). Furthermore, loss of *p53* not only abolished the inhibitory effect of *Fanca* deficiency but also further boosted glucose uptake (Fig. 2C) and lactate production (Fig. 2D). These results suggest a novel metabolic reprogramming by which FA deficiency collaborates with p53 in suppressing glycolysis.

p53-TIGAR Attenuates ROS, DNA Damage, and Chromosomal Instability in FA HSPCs

To understand the role of p53-TIGAR-mediated glycolytic suppression in FA HSCs, we first determined p53 activation in *Fanca*^{-/-} HSPCs. We observed increased phosphorylation of p53 at Serine 18 (p53^{Ser18}), an established marker for p53 activation [38, 39], in *Fanca*^{-/-} BM LSK cells compared with WT cells (Fig. 3A).

To specifically explore the function of TIGAR in glycolytic suppression in the context of FA cellular deficiency, we ectopically expressed mCherry or mCherry-TIGAR in WT, *Fanca*^{-/-}, *p53*^{-/-}, and *Fanca*^{-/-}*p53*^{-/-} DKO LSK cells (Fig. 3B). Quantitative PCR (q-PCR) analysis shows that the sorted mCherry⁺ cells overexpressed TIGAR (Fig. 3C). Since TIGAR suppresses glycolysis and promotes the pentose phosphate pathway (PPP), leading to increase in NADPH production and reduction of reactive oxygen species (ROS) [40], we first measured intracellular ROS level. Flow cytometry analysis showed that ROS levels in *p53*^{-/-} and *p53*^{-/-}*Fanca*^{-/-} DKO HSCs were remarkably higher than those in WT and *Fanca*^{-/-} controls (Fig. 3D). Forced expression of TIGAR markedly reduced ROS production in *p53*^{-/-} and *p53*^{-/-}*Fanca*^{-/-} DKO HSCs (Fig. 3D). TIGAR expression also reduced ROS in WT and *Fanca*^{-/-} cells, albeit not statistically significant when compared with their mCherry controls (Fig. 3D). Consequently, ectopic expression of TIGAR markedly reduced DNA damage in *p53*^{-/-} and *p53*^{-/-}*Fanca*^{-/-} DKO HSPCs and, to a less extent in *Fanca*^{-/-} cells, as determined by immunoblotting for γ-H2AX, a robust marker of DNA double-strand breaks ([41]; Fig. 3E). Furthermore, overexpression of TIGAR significantly reduced spontaneous chromosomal breakage in *Fanca*^{-/-}, *p53*^{-/-}, and *p53*^{-/-}*Fanca*^{-/-} DKO LSK cells (Fig. 3F).

It is well established that TIGAR has fructose-2,6-bisphosphatase activity, which depletes Fru-2,6-BP, resulting in inhibition of glycolysis and thus directing the pathway into the pentose

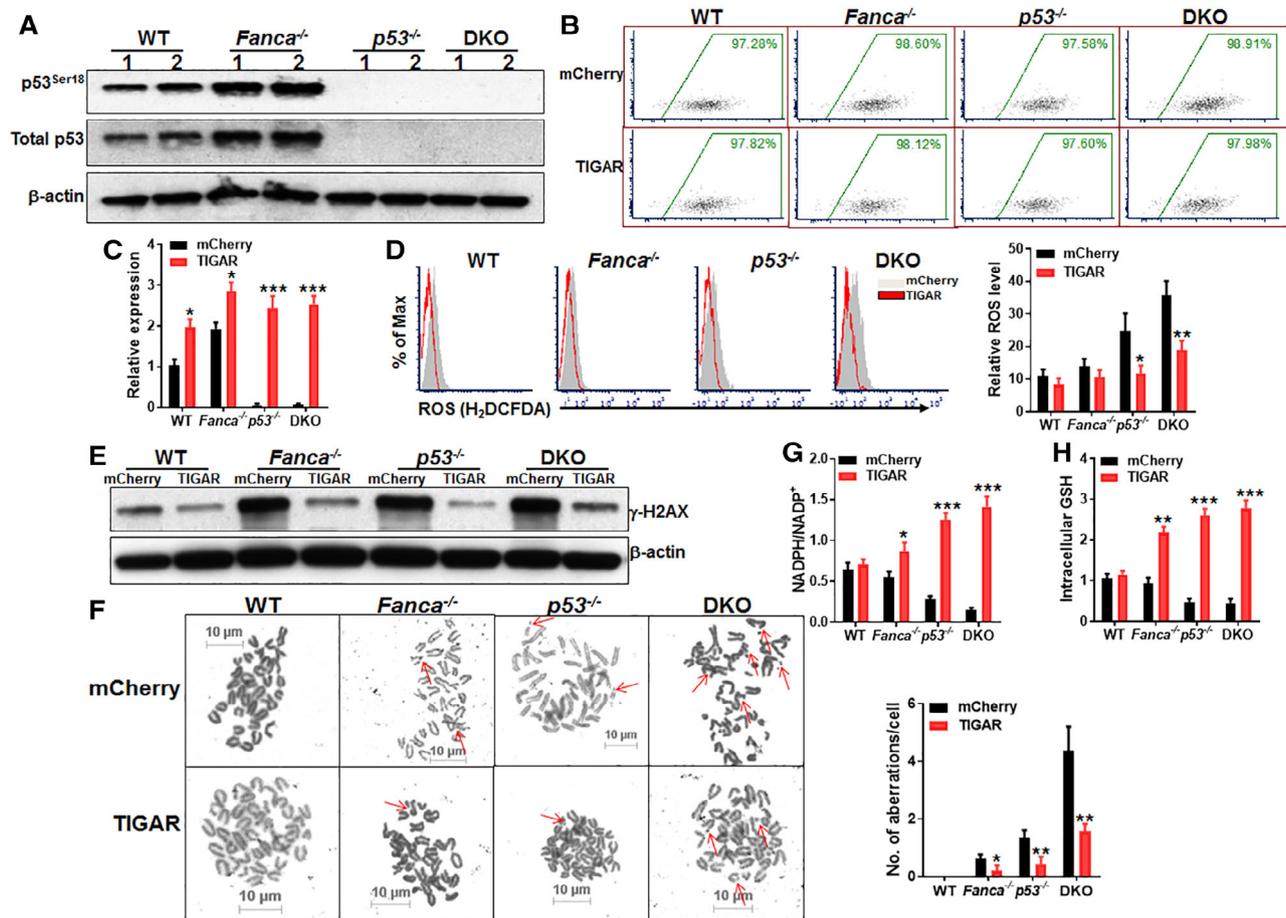

Figure 3. p53-TP53-induced glycolysis regulator (TIGAR)-mediated glycolytic suppression attenuates reactive oxygen species (ROS), DNA damage, and chromosomal instability in Fanconi anemia (FA) HSPCs. **(A):** Overactivation of p53 in FA HSPCs. Whole cell lysates (WCLs) were extracted from Lineage⁺Sca-1⁺c-kit⁺ (LSK) cells isolated from wild-type (WT), *Fanca*^{-/-}, *p53*^{-/-}, or *p53*^{-/-}*Fanca*^{-/-} mice followed by Western blotting using antibodies against total p53, p53^{Ser18}, and β -actin. **(B):** Lentiviral transduction and FACS sorting. LSK cells isolated from WT, *Fanca*^{-/-}, *p53*^{-/-}, or *p53*^{-/-}*Fanca*^{-/-} mice were transduced with lentiviral vector expressing mCherry or mCherry-TIGAR. Flow plots after FACS sorting for mCherry are shown. The sorted mCherry⁺ cells were then subjected to ex vivo expansion for 72 hours followed by the analyses described below. **(C):** Expression of TIGAR in transduced HSCs. RNA was extracted from mCherry⁺ SLAM cells described in (B) were subjected to quantitative polymerase chain reaction analysis for TIGAR expression. Samples were normalized to the level of GAPDH mRNA. **(D):** Overexpression of TIGAR reduces ROS level in HSCs. Cells described in (B) were gated for mCherry⁺ SLAM population and subjected to flow cytometry analysis for ROS. Representative plots (left) and quantification (right) are shown. **(E):** Overexpression of TIGAR reduces DNA damage in FA HSPCs. phosphate shunt to produce NADPH and reduce ROS [24,26]. Indeed, overexpression of TIGAR enhanced the PPP and cellular antioxidant function in *Fanca*^{-/-}, *p53*^{-/-}, and *p53*^{-/-}*Fanca*^{-/-} DKO HSPCs evidenced by increased NADPH/NADP⁺ ratio and intracellular GSH level in TIGAR-expressing cells compared with the cells expressing mCherry only (Fig. 3G, 3H). Together, these findings indicate that p53-TIGAR-mediated glycolytic suppression attenuates DNA damage and chromosomal instability in FA HSPCs through promoting the PPP pathway and enhancing cellular antioxidant function.

p53-TIGAR Ameliorates Exhaustion of FA HSCs

To determine the role of p53-TIGAR in FA HSC function, we first performed a well-established CRU assays using limiting dilutions of LSK cells expressing mCherry or mCherry-TIGAR from WT,

Fanca^{-/-}, *p53*^{-/-}, and *Fanca*^{-/-}*p53*^{-/-} DKO mice. Increasing doses of transduced LSK cells (25, 75, 150, and 250 mCherry⁺ cells) along with protector BM cells were transplanted into lethally irradiated Boyl mice. PB samples were collected at 8 and 16 weeks post-transplantation and analyzed for donor engraftment. Consistent with previous report, in which the reduced long-term repopulation of *p53*^{-/-} SLAM was shown by a CRU assays [42], we constantly observed the decreased donor-derived cells in both primary and secondary recipients injected with *p53*^{-/-} LSK cells 4 months post-bone marrow transplant, which can be arguably considered long-term repopulation. Poisson statistical analysis at 8 weeks post-transplant showed >fivefold reduction in CRUs in DKO mice than in WT mice (CRUs: 1 in 28 for WT-mCherry compared with 1 in 142.9 for DKO-mCherry; Fig. 4A). This reduction in CRUs in DKO mice was found further increased

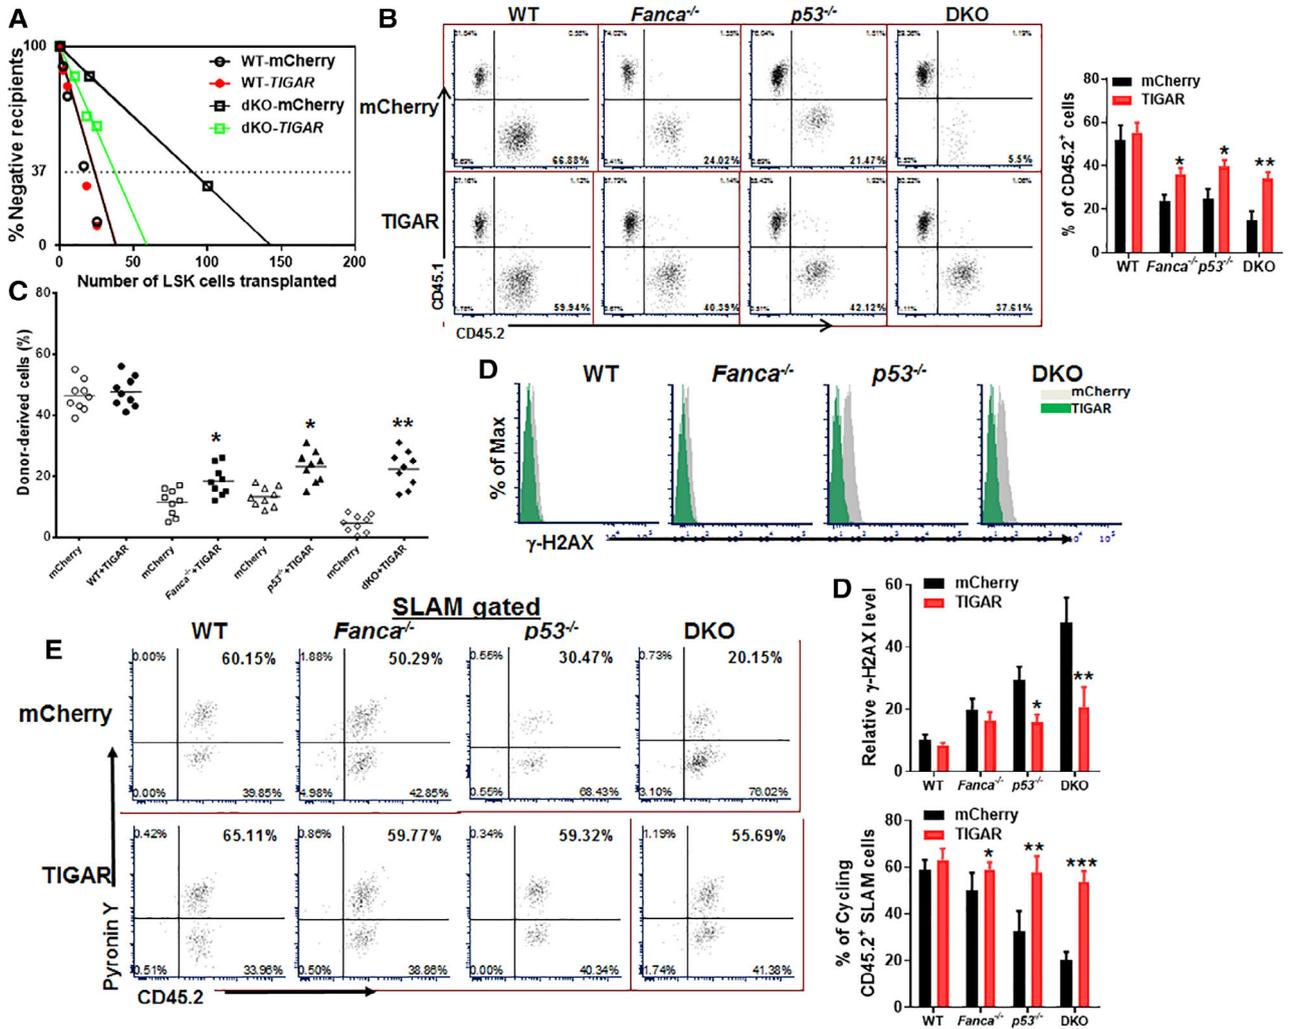

Figure 4. p53-TP53-induced glycolysis regulator (TIGAR) ameliorates exhaustion of Fanconi anemia (FA) hematopoietic stem cells (HSCs). **(A):** Limited dilution assay. Various doses of sorted transduced Lineage⁻Sca-1⁺c-kit⁺ (LSK) cells (25, 75, 150, and 250 mCherry⁺ cells) expressing mCherry or mCherry-TIGAR were mixed with 2×10^6 protector bone marrow (BM) cells (CD45.1⁺) and transplanted into irradiated congenic recipients ($n = 8-10$ per group). Plotted are the percentages of recipient mice containing <1% CD45.2⁺ blood nucleated cells (negative) at 8 weeks after transplantation. Frequency of functional HSCs was calculated according to Poisson statistics. **(B):** Overexpression of TIGAR improves hematopoiesis reconstitution capacity of FA HSPCs. One thousand sorted mCherry or mCherry-TIGAR lentiviral vector transduced LSK cells were transplanted into lethally irradiated BoyJ mice. The recipients were subjected to flow cytometry analysis for donor-derived cells 16 weeks after BM transplantation. Representative flow plots (left) and quantification (right) are shown ($n = 9$ per group). **(C):** Overexpression of TIGAR improves long-term repopulating activity of FA HSCs. One million BM cells from the primary recipient mice described in (B) were transplanted into sublethally irradiated secondary CD45.1⁺ recipient mice and donor-derived chimera in secondary recipients were determined by flow cytometry 16 weeks later ($n = 9$ per group). **(D):** Overexpression of TIGAR reduces DNA damage in donor cells. CD45.2⁺ LSK cells from the recipients described in (B) were subjected to flow cytometry analysis for γ -H2AX. Representative plots (upper) and quantification (lower) are shown. **(E):** Overexpression of TIGAR increases donor HSC quiescence. Percentage of Pyronin Y⁺ cells in donor HSC compartment (CD45.2⁺ SLAM) was analyzed by flow cytometry. Representative flow plots (left) and quantification (right) are shown ($n = 6$ per group); *, $p < .05$; **, $p < .01$; ***, $p < .001$.

Table 1. Competitive repopulating units

Genotype	WT		<i>Fanca</i> ^{-/-}		<i>p53</i> ^{-/-}		<i>Fanca</i> ^{-/-} ; <i>p53</i> ^{-/-}	
	mCherry	TIGAR	mCherry	TIGAR	mCherry	TIGAR	mCherry	TIGAR

$n = 8-10$ per group.

to >30-fold when estimated at 16 weeks post-transplantation (CRUs: 1 in 14.2 for WT-mCherry compared with 1 in 442 for DKO-mCherry; Table 1). Forced expression of TIGAR significantly increased CRUs in *Fanca*^{-/-}, *p53*^{-/-}, and *Fanca*^{-/-}*p53*^{-/-} DKO mice compared with WT controls at both 8 weeks and 16 weeks post-

transplant (Table 1; Fig. 4A). These results indicate that the p53-TIGAR metabolic axis plays an important role in ameliorating exhaustion of FA HSCs, a hallmark of FA BM failure [6, 42].

We next performed serial BM transplantation experiments by transplanting 1,000 mCherry⁺ LSK cells into lethally irradiated

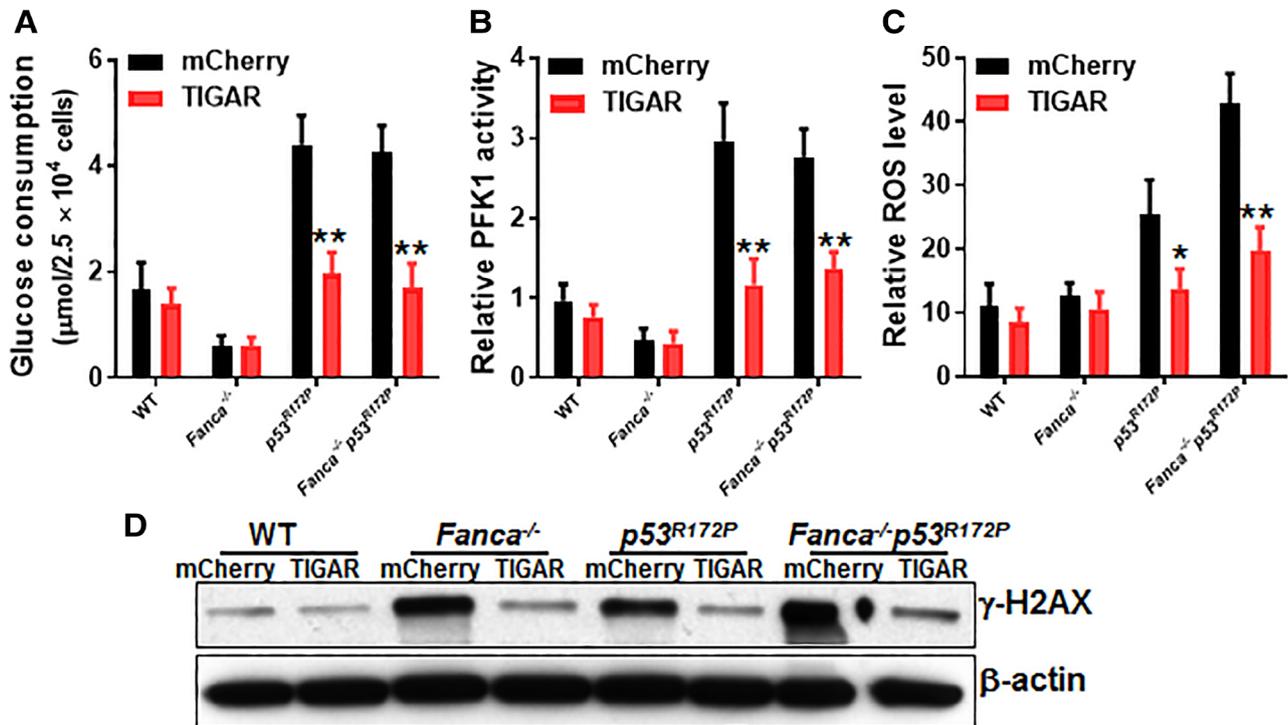

Figure 5. p53-Dependent cell-cycle control is not required for TP53-induced glycolysis regulator (TIGAR)-mediated metabolic reprogramming. **(A):** Overexpression of *TIGAR* reduces glucose consumption in $p53^{R172P}$ hematopoietic stem cells (HSCs). Bone marrow Lineage⁺Sca-1⁺c-kit⁺ cells from wild-type, $Fanca^{-/-}$, $p53^{R172P}$, and $Fanca^{-/-}p53^{R172P}$ mice were transduced with lentivirus expressing mCherry-*TIGAR* or mCherry alone. The sorted mCherry⁺ cells were expanded for 72 hours. The transduced cells were gated for mCherry⁺ SLAM population and assayed for glucose consumption. **(B):** Overexpression of *TIGAR* reduces PFK1 activity in $p53^{R172P}$ HSPCs. Cells described in (A) were gated for mCherry⁺ population and assayed for PFK1 activity. **(C):** Overexpression of *TIGAR* reduces ROS production in $p53^{R172P}$ HSPCs. Cells described in (A) were gated for mCherry⁺ SLAM population and analyzed for intracellular ROS by flow cytometry ($n = 6$ per group). **(D):** Overexpression of *TIGAR* reduces DNA damage in $p53^{R172P}$ HSPCs. WCLs were extracted from mCherry⁺ cells described in (A) followed by Western blotting using antibodies against γ -H2AX and β -actin. Results depicted in (A) and (B) are means \pm SD of three independent experiments; *, $p < .05$; **, $p < .01$.

syngeneic recipient mice. We found that overexpression of TIGAR significantly improved the repopulating capacities of $Fanca^{-/-}$, $p53^{-/-}$, and $Fanca^{-/-}p53^{-/-}$ DKO HSCs in primary recipient mice at 16 weeks post-transplantation (Fig. 4B). Noticeably, alteration of p53-TIGAR axis did not affect lineage differentiation in the recipient mice (Supporting Information Fig. S3). Similar results were observed in secondary transplantation, in which TIGAR enhanced the repopulating capacity of the donor-derived $Fanca^{-/-}$, $p53^{-/-}$, and $Fanca^{-/-}p53^{-/-}$ DKO HSCs, as compared with mCherry controls (Fig. 4C). Significantly, overexpression of TIGAR reduced the levels of γ H2AX in donor-derived $Fanca^{-/-}$, $p53^{-/-}$, and $Fanca^{-/-}p53^{-/-}$ DKO HSCs (Fig. 4D). Furthermore, cell-cycle analysis showed that TIGAR-expressing $Fanca^{-/-}$, $p53^{-/-}$, or $p53^{-/-}Fanca^{-/-}$ HSCs were more quiescent than those expressing mCherry only (Fig. 4E). Therefore, these data suggest that p53-TIGAR attenuates FA HSC exhaustion by reducing DNA damage and maintaining HSC quiescence.

p53-Dependent Cell-Cycle Control Is Not Required for TIGAR-Mediated Metabolic Reprogramming

Because deletion of *p53* reduced the quiescence of $Fanca^{-/-}$ HSCs (Fig. 4E), we wondered if the effect of TIGAR was specifically dependent on the cell-cycle function of p53. We recently demonstrated a cell-cycle-specific function of p53 in FA HSPC proliferation [42], using a mutant p53 mouse strain harboring a separation-of-function mutation in p53, $p53^{R172P}$, in which its

apoptotic function is disturbed but its cell-cycle checkpoint activities remain intact [28]. Thus, we crossed the $p53^{R172P}$ strain to $Fanca^{-/-}$ mice and transduced LSK cells from the mice of the resulting four genotypes (WT, $Fanca^{-/-}$, $p53^{R172P}$, and $Fanca^{-/-}p53^{R172P}$) with lentivirus expressing mCherry-*TIGAR* or mCherry alone. Similar to p53-null mutation, we found that $p53^{R172P}$ mutation significantly increased glucose consumption in $Fanca^{-/-}$ HSCs and that forced expression of *TIGAR* reduced glucose consumption to near WT levels (Fig. 5A). Similar results were obtained with the measurements of PFK1 activity (Fig. 5B), intracellular ROS (Fig. 5C), and DNA damage (Fig. 5D). These data indicate that the cell-cycle function of p53 is not required for TIGAR-mediated metabolic reprogramming in HSCs.

PFKFB3 Specifically Antagonizes p53-TIGAR Metabolic Function in FA HSCs

Both TIGAR and another rate-limiting enzyme, PFKFB3, play critical roles in controlling glycolytic flux, which is adjusted by the level of fructose 2,6-bisphosphate (F2,6BP). F2,6BP activates PFK1 and is by itself synthesized and degraded by a family of biofunctional enzymes, the PFKFB [43]. Of all PFKFB isoenzymes, PFKFB3 exhibits a much higher (700-fold) kinase activity than bisphosphatase activity, thus favoring F2,6BP production and controlling its abundance [37,44]. On the other hand, TIGAR functions as a fructose-2,6-bisphosphatase and therefore lowering the activity of PFK1 and flux through the

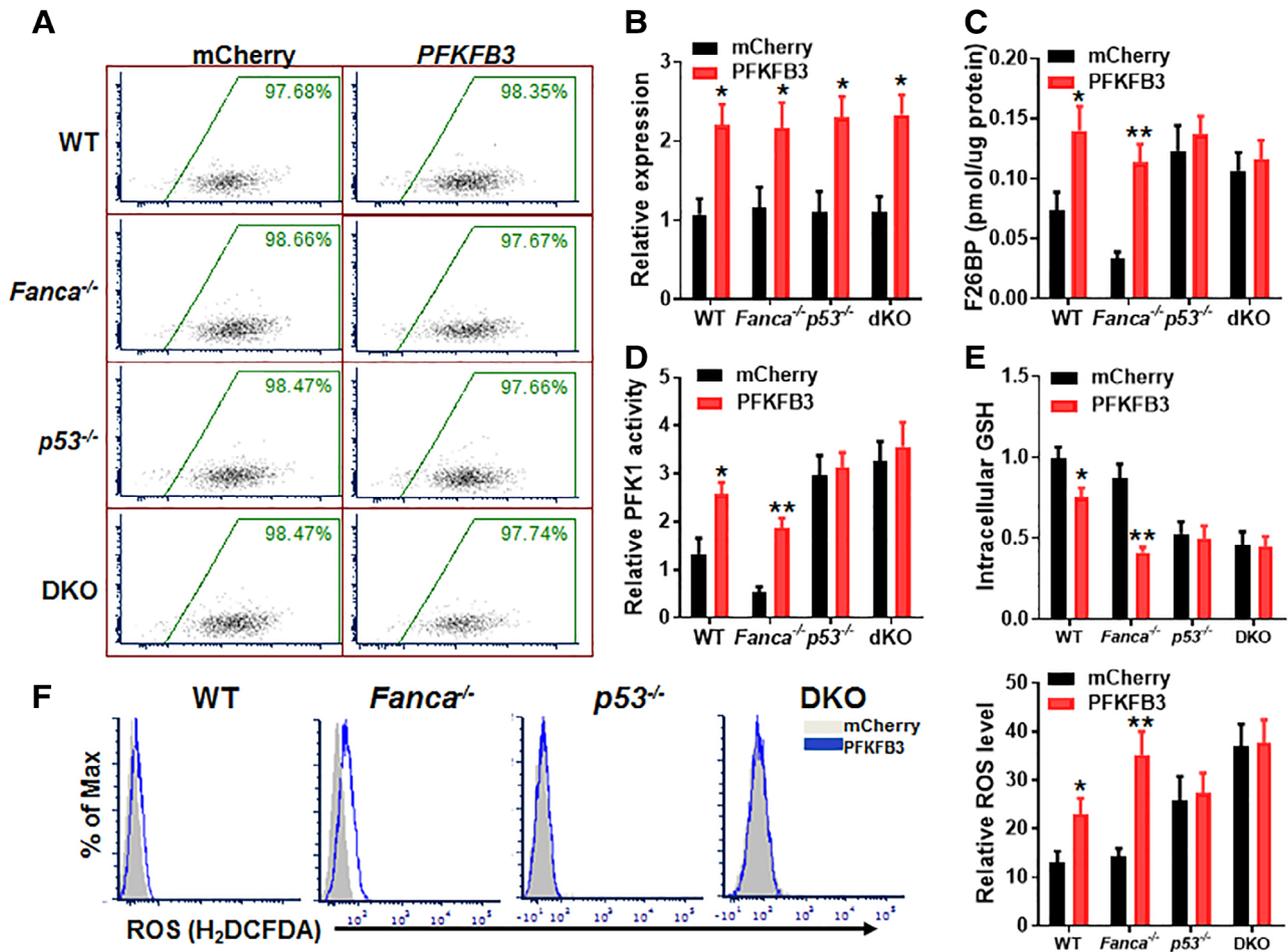

Figure 6. PFKFB3 specifically antagonizes p53-TP53-induced glycolysis regulator metabolic function in Fanconi anemia (FA) hematopoietic stem cells (HSCs). **(A):** Lentiviral mCherry-PFKFB3 transduction and FACS sorting. LSK cells isolated from wild-type, *Fanca*^{-/-}, *p53*^{-/-}, or *p53*^{-/-}/*Fanca*^{-/-} mice were transduced with lentiviral vector expressing mCherry or mCherry-PFKFB3. Flow plots after FACS sorting for mCherry are shown. The sorted mCherry⁺ cells were then subjected to ex vivo expansion for 72 hours followed by the analyses described below. **(B):** Expression of *PFKFB3* in transduced HSCs. Cells described in (A) were gated for mCherry⁺ SLAM population and RNA was extracted for q-PCR analysis for *PFKFB3* expression. Samples were normalized to the level of *GAPDH* mRNA ($n = 6$ per group). **(C):** Overexpression of *PFKFB3* increases Fru-2,6-BP production. Cells described in (A) were gated for mCherry⁺ SLAM population and analyzed for F26BP by MicroAssay. **(D):** Overexpression of *PFKFB3* increases PFK1 activity. Cells described in (A) were gated for mCherry⁺ population and subjected to analysis for PFK1 activity. **(E):** Overexpression of *PFKFB3* increases intracellular GSH. Cells described in (A) were gated for mCherry⁺ population and subjected to GSH assay. **(F):** Overexpression of *PFKFB3* increases ROS. Cells described in (A) were gated for mCherry⁺ population and subjected to analysis for ROS by flow cytometry. Representative plots (left) and quantification (right) are shown ($n = 6$ per group); *, $p < .05$; **, $p < .01$.

main glycolytic pathway, leading to increase in fructose-6-phosphate [16, 17, 40]. Given its closely relative role in regulating glycolytic flux, we wondered whether increased expression of PFKFB3 could counteract p53-TIGAR function in FA HSCs. Ectopic expression of PFKFB3 in WT and *Fanca*^{-/-}, *p53*^{-/-}, and DKO LSK cells was achieved by lentiviral transduction (Fig. 6A, 6B). We found that overexpression of PFKFB3 increased F2,6BP levels in WT and *Fanca*^{-/-} SLAM cells but had no further effect on F2,6BP in *p53*^{-/-} or DKO HSCs (Fig. 6C). Consistently, PFK1 activity was increased in PFKFB3-overexpressing WT or *Fanca*^{-/-} HSPCs but not in *p53*^{-/-} or DKO cells (Fig. 6D). Furthermore, overexpression of PFKFB3 decreased intracellular levels of GSH in WT and *Fanca*^{-/-} mCherry⁺ cells but not in HSPCs deleted for p53 (*p53*^{-/-} and DKO; Fig. 6E). Consequently, intracellular ROS were significantly increased in PFKFB3-overexpressing WT or *Fanca*^{-/-} HSCs but not in *p53*-deficient cells (Fig. 6F). These results indicate that PFKFB3 specifically antagonizes p53-TIGAR metabolic function in HSCs.

DISCUSSION

This study provides several pieces of evidence that the p53-TIGAR metabolic axis suppresses glycolysis, which serves to enhance the competitive fitness of FA HSCs. Specifically, we show that (a) compared with WT HSCs, FA HSCs exhibit a p53-TIGAR-dependent glycolytic suppression; (b) the p53-TIGAR metabolic axis functions to ameliorate FA HSC exhaustion; (c) p53-TIGAR-dependent glycolytic suppression attenuates ROS, DNA damage, and chromosomal instability in FA HSCs; (d) although the p53-TIGAR metabolic axis is essential for maintaining FA HSC quiescence, p53-dependent cell-cycle control is not required for metabolic reprogramming in FA HSCs; (e) the rate-limiting glycolytic enzyme PFKFB3 specifically antagonists p53-TIGAR metabolic function in FA HSCs.

Glycolysis is the preferential metabolic program utilized by HSCs to produce ATP, whereas mitochondrial OXPHOS is more active in hematopoietic progenitors [43]. One interesting observation of our study is that the reduced glycolysis is

restricted in FA HSC compartment but not in the less primitive MPPs (Lin⁻Sca1⁺c-kit⁺CD150⁻CD48⁻), HPCs (Lin⁻Sca1⁺c-kit⁺CD150⁻CD48⁺ and Lin⁻Sca1⁺c-kit⁺CD150⁺CD48⁺), or Lin⁺ cells. This is consistent with our previous study that shows that FA HSCs are more dependent on OXPHOS relative to glycolysis in their resting state for energy metabolism [12]. Whether this abnormal metabolic reprogramming in FA HSCs contributes to clinical hematological symptoms in FA such as BM failure and leukemogenesis remain to be defined. Nevertheless, altered metabolic energetics has been demonstrated in HSCs at different stages of their life cycle and in certain blood disorders [45–47]. In this context, new insights into the metabolic differences between normal and diseased HSCs may prove valuable for developing better therapeutic strategies for hematologic diseases like BM failure and leukemia.

It is known that p53 regulates energy metabolism at both glycolytic and OXPHOS steps through transcriptional regulation of its target genes *TIGAR* and *SCO2* (*synthesis of cytochrome c oxidase*; [23, 24]). *TIGAR* shares functional sequence similarities with the bis-phosphatase domain (FBPase-2) of the bi-functional enzyme PFK-2/FBPase-2, which degrades fructose-2,6-bisphosphate (Fru-2,6-BP). Fru-2,6-BP can induce 6-phospho-1-kinase (PFK1), which is required for the conversion of fructose-6-phosphate to fructose-1,6-bisphosphate at the third step of the cellular glycolysis reaction [48]. *TIGAR* thus reduces the cellular levels of Fru-2,6-BP and thereby blocks glycolysis at this rate-limiting step. We observed an overactivated p53-TIGAR metabolic axis in HSCs from *Fanca*^{-/-} and *Fancc*^{-/-} mice (Figs. 1, 2). This may explain why FA HSCs switch to OXPHOS for energy metabolism [12]. Ectopic expression of *TIGAR* directs the metabolism of cellular glucose through enhancing the PPP and cellular antioxidant function, therefore reducing DNA damage and chromosomal breakages in FA HSCs (Figs. 3, 4). These results suggest that p53-TIGAR metabolic axis-mediated glycolytic suppression may play a compensatory role in attenuating DNA damage and genomic instability in FA HSCs. Indeed, inactivation of the p53-TIGAR metabolic axis by deleting p53 in *Fanca*^{-/-} mice induced premature HSC exhaustion (Fig. 4). Thus, our study identifies a novel role of the p53-TIGAR metabolic axis in genomic maintenance.

PFKFB3 has been distinguished from the other PFKFB isoenzymes by its high kinase to bisphosphatase ratio. Overexpression of PFKFB3 in transformed cells has identified it as a powerful glycolytic activator [44, 48]. Our data suggest that PFKFB3 could counteract p53-TIGAR function in FA HSCs. PFKFB3 synthesizes F26BP, an allosteric stimulator of PFK-1 which is another potent activator of glycolysis [37]. Although we observed no difference in PFKFB3 mRNA levels between WT and FA HSCs (Fig. 1), the levels of F26BP and PFK1 enzyme activity were significantly lower in FA HSCs than in WT cells (Figs. 2, 6). Importantly, we showed that overexpression of PFKFB3 increased F2,6BP and PFK1 activity, decreased intracellular GSH, and consequently increased ROS in WT and *Fanca*^{-/-} HSCs but had no further effect on these glycolytic stimulators or DNA-damaging substances in HSCs deleted for p53 (*p53*^{-/-} and DKO; Fig. 6). These results suggest that PFKFB3 specifically antagonizes p53-TIGAR metabolic reprogramming in FA HSCs. Although further studies are required to reveal the underlying molecular mechanisms, we employed a separation-of-function

mutant p53 mouse model to demonstrate that the cell-cycle function of p53 is not required for its metabolic reprogramming in FA HSCs. This is especially intriguing, given that the p53-TIGAR metabolic axis acted to preserve FA HSC quiescence (Fig. 4). The role of p53 in both apoptosis and cell-cycle arrest have been well established. Recent study suggests that p53 downregulates the FA DNA repair pathway [49]. It has also been shown that BM failure in FA is triggered by an exacerbated p53/p21 DNA damage response that impairs HSPCs [50]. We recently demonstrated a cell-cycle specific function of p53 in FA HSPC proliferation and proposed that overactivated p53 might represent a compensatory checkpoint mechanism for FA HSC proliferation [42]. However, our present study shows that *Fanca*^{-/-} HSCs carrying the *p53*^{R172P} mutation exhibited increased glucose consumption and PFK1 activity (Fig. 5), exactly as observed in p53-null *Fanca*^{-/-} HSCs (Fig. 2), suggesting that the cell-cycle activity of p53 is not required for *TIGAR*-mediated glycolytic suppression in FA HSCs.

CONCLUSION

By employing a model of FA, we showed that p53-TIGAR-mediated glycolytic suppression attenuates ROS production, reduces DNA damage, ameliorates chromosomal instability, and consequently prevents premature exhaustion of FA HSCs. Our findings reveal a novel function of the p53-TIGAR metabolic axis in the maintenance of FA HSCs.
