## ABSTRACT

**Background:** The efficacy and safety of 5 $\alpha$ -reductase inhibitors (5ARIs) in treating prostate cancer (PCa) have not been fully determined. We performed a meta-analysis to evaluate the effectiveness and safety of 5ARIs for PCa patients.

**Methods:** A comprehensive literature search of online databases was conducted to obtain comparative studies exploring the effectiveness and safety of 5ARIs in treating PCa up to October 2019. Summarized odds ratios (ORs) or hazard ratios (HRs) were calculated to compare the outcomes between 5ARI and control groups.

Our meta-analysis was registered in PROSPERO under number CRD42018109809.

**Results:** A total of 2,277 patients from 10 studies were included. No significant difference was found in prostate-specific antigen progression between two groups (OR = 0.82, 95% CI [0.52–1.29],  $P = 0.40$ ). However, 5ARI treatment significantly reduced the total progression of PCa (OR = 0.61, 95% CI [0.48–0.77],  $P < 0.0001$ ), especially for patients with local (OR = 0.56, 95% CI [0.44–0.73],  $P < 0.00001$ ) and low-Gleason score ( $\leq 7$ ) PCa (OR = 0.63, 95% CI [0.48–0.84],  $P = 0.002$ ).

Additionally, 5ARIs also significantly prolonged the progression-free survival time (HR = 0.57, 95% CI [0.34–0.96],  $P = 0.04$ ) for PCa patients. No significant difference was found in the occurrence of PCa recurrence, metastasis, biopsy reclassification, and side-effects between two groups.

**Conclusions:** Our study suggests that 5ARI treatment can benefit patients with local and low Gleason score ( $\leq 7$ ) PCa, especially in delaying the disease progression. More studies with larger sample size and comprehensive study design are still needed to verify our outcomes.

## INTRODUCTION

Prostate cancer (PCa) is the second most common cancer and the fifth leading cause of cancer mortality in men all over the world. Approximately 1.3 million new cases and 359,000 associated deaths existed worldwide in 2018 (Bray *et al.*, 2018). In US, the incidence of PCa is highest in cancer and its related death also ranks the second among

OPEN ACCESS

male patients. Based on the data, 164,690 new cases and 29,430 deaths are estimated to emerge in the following year (Siegel, Miller & Jemal, 2018). Several therapeutic strategies were used for the management of PCa, including active surveillance (AS), surgery, radiotherapy (RT), hormonal therapy and chemotherapy (Litwin & Tan, 2017). Besides, 5 $\alpha$ -reductase inhibitors (5ARIs), such as finasteride and dutasteride, play an important role in treating benign prostatic hyperplasia (BPH) by blocking 5 $\alpha$ -reductase and inhibiting testosterone conversion to dihydrotestosterone (McConnell et al., 1992). For the prevention of PCa, the efficacy of 5ARIs has been reported in many studies (Andriole et al., 2010, 2004; Thompson et al., 2003). Results from randomized clinical trials (RCTs) showed that the incidence of PCa was lower in patients receiving 5ARIs compared with those taking placebo (Andriole et al., 2010, 2004; Thompson et al., 2003).

However, the efficacy and safety of 5ARIs in treating the PCa has not been fully researched. Previous studies reported that PCa patients treated with combined flutamide and finasteride had a significantly lower progression risk than those with flutamide alone (Banez et al., 2009). In low-risk PCa, 5ARIs led to lower rates of pathologic progression and aggressive treatments in patients receiving AS (Finelli et al., 2011; Fleshner et al., 2012). Contradictorily, recent studies demonstrated that 5ARIs did not benefit the grade reclassification and pathologic progression for PCa patients on AS (Dai et al., 2018; Ozkan et al., 2018). Adding dutasteride to bicalutamide also could not delay the disease progression in patients with non-metastatic castration-resistant prostate cancer (CRPC) (Chu et al., 2015). Therefore, the effectiveness of 5ARIs for treating PCa is still controversial. Furthermore, 5ARIs for treating PCa are not recommended in either European Association of Urology (EAU) or American Urological Association (AUA) guidelines due to inadequate high-level evidences. Although one meta-analysis was published recently exploring the association between 5ARIs therapy and PCa, it mainly focused on PCa's incidence and only two studies were included to evaluate the effect of 5ARI therapy on PCa progression (Luo et al., 2019). We performed this meta-analysis on published literature to evaluate the effectiveness, safety, and potential advantages of 5ARIs in the treatment of PCa.

## MATERIALS AND METHODS

This meta-analysis was conducted meeting the criteria of Preferred Reporting Items for Systematic Reviews and Meta-analysis (PRISMA) guidelines. Protocol of this study was registered in PROSPERO under number CRD42018109809.

### PICOS question

Patient, intervention, comparison, outcome, and study design (PICOS) guided the main question of this review: does 5ARI treatment (Intervention) improve the prognosis (PSA progression, total progression, progression-free survival time and side-effects) (Outcome) of PCa patients (Patient) compared with those who did not receive these treatments (Comparison)?

### Search strategy

Potential comparative trials studying treatment effects of 5ARIs for PCa were searched comprehensively using electronic databases, such as the Pubmed, Embase, Medline and Cochrane Library. The last search was in October, 2019. All references of included studies were also carefully checked. Language was restricted to English on eligible studies. We applied the following search terms to obtain original studies: “5alpha-reductase inhibitors” or “5-alpha reductase inhibitors” or “5ARIs” or “finasteride” or “dutasteride” in combination with “prostate cancer” or “prostate carcinoma”. Two authors (Tuo Deng and Xueming Lin) independently performed literature search and screening, quality assessment of eligible studies and data extraction. Disagreements were resolved by discussing with the third author (Guohua Zeng).

### Inclusion and exclusion criteria

Studies were included on the basis of the following criteria: (1) Studies should compare the effects of 5ARI and non-5ARI treatments for PCa patients; (2) 5ARIs should be applied after PCa diagnosis; (3) At least one prognostic outcome could be achieved, such as progression, recurrence, metastasis, progression-free survival and so on. Accordingly, studies with participants receiving 5ARIs before PCa diagnosis were excluded from this analysis. Meanwhile, abstracts, case reports, conference proceedings, non-published materials, editorials, reviews, animal experiments and repeated publications were also excluded.

### Quality assessment and data extraction

The level of evidence (LOE) of all included studies was assessed by the criteria from the Oxford Centre for Evidence-based Medicine. The quality of RCTs was evaluated using the Cochrane risk of bias tool, and the Newcastle-Ottawa Scale (NOS) was applied for the quality of non-RCTs.

Data from original studies was attentively extracted as follows: first author, year of publication, study country, population, period of recruitment, research methodology, type of PCa, tumor stage, Gleason score, previous therapy, type of 5ARIs, characteristics of participants, detailed 5ARIs treating strategy, follow-up time, and related outcomes. When incomplete data existed, we contacted authors of these studies.

### Outcome and statistical analysis

Primary outcomes of this analysis were PSA progression, total progression, progression-free survival time and side-effects. Secondary outcomes included recurrence, metastasis, biopsy reclassification during treatments and therapeutic response. PSA progression was defined as PSA value >20 ng/ml (for subjects who received no previous therapies or underwent primary RT) or >10 ng/ml (for subjects who underwent radical prostatectomy (RP) with or without salvage RT) associated with a 50% increase in PSA from baseline. Total progression referred to patients experiencing any PCa progression, including PSA progression, pathologic progression (having at least one of the predefined criteria: cancer involving  $\geq 3$  cores, Gleason pattern score  $\geq 4$ , or  $\geq 50\%$  of any

one core involved), clinical symptoms of progression, and therapeutic progression (defined as necessary post-baseline rescue therapies or medications).

Summarized odds ratios (ORs) with 95% confidence intervals (CIs) were calculated to compare dichotomous variables. Multivariable adjusted hazard ratios (HRs) of 5ARIs were also pooled for predicting progression-free survival in eligible studies. The chi-square test-based  $Q$ - and  $I^2$ - statistic was used to test heterogeneity among studies. If heterogeneity was not significant with a  $P$  value  $> 0.10$ , the fixed-effect model was used; otherwise, the random-effect was applied. Significant results were considered with a two-sided  $P$  value  $< 0.05$ . For possible studies, we performed subgroup analyses according to study population, study design, tumor type, Gleason score, previous therapy, and 5ARI type. The publication bias was assessed through the inverted funnel plot visual inspection and Egger's test. All statistical analyses were done by RevMan (version 5.3; Cochrane Collaboration, Oxford, UK) and STATA (version 13.0; StataCorp., College Station, TX, USA).

## RESULTS

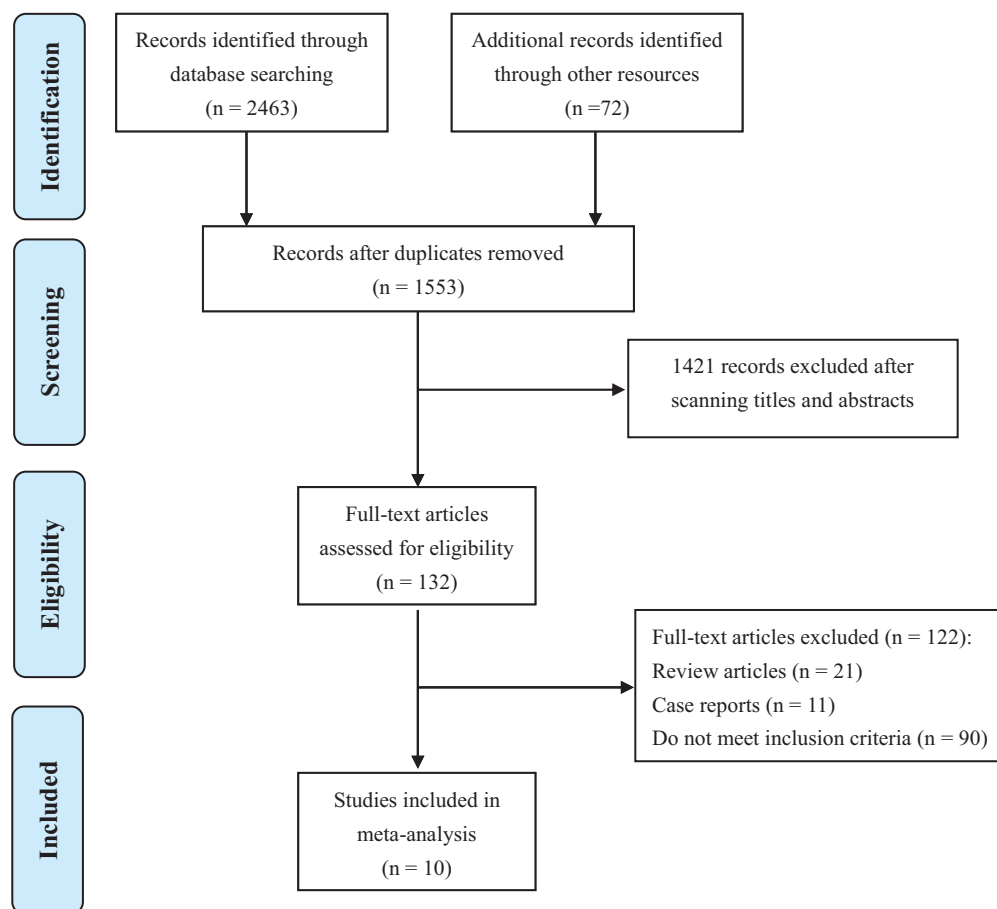

### Characteristics and quality assessment of eligible studies

Ten studies (*Andriole et al., 1995; Banez et al., 2009; Chu et al., 2015; Dai et al., 2018; Dutkiewicz, 2012; Finelli et al., 2011; Fleshner et al., 2012; Ozkan et al., 2018; Ross et al., 2012; Schroder et al., 2013*) containing 2,277 PCa patients were involved in this analysis (Fig. 1). Basic characteristics were shown in Table 1. Most studies were conducted in America or Europe. All literature was published between 1995 to 2018. Among them, five were RCTs (*Andriole et al., 1995; Chu et al., 2015; Dutkiewicz, 2012; Fleshner et al., 2012; Schroder et al., 2013*), one was prospective cohort study (*Banez et al., 2009*), and other four were retrospective cohort studies (*Dai et al., 2018; Finelli et al., 2011; Ozkan et al., 2018; Ross et al., 2012*). Most studies focused on local PCa, while metastatic PCa (*Dutkiewicz, 2012*) and non-metastatic CRPC (*Chu et al., 2015*) were investigated in only one study respectively. Therapies that PCa patients received prior to recruitments included RP, RT, AS or no treatments. 5ARIs used in these studies were finasteride or dutasteride. In total, 694 patients were allocated to 5ARI group, and 1,583 patients belonged to the control group. Detailed treatment strategies in 5ARI and control groups for each study were also listed in Table 1.

The LOE of all eligible studies was shown in Table 1. For RCTs, four (*Andriole et al., 1995; Chu et al., 2015; Fleshner et al., 2012; Schroder et al., 2013*) were evaluated as high-quality studies with a low risk of bias according to the Cochrane risk of bias tool. Biases of allocation concealment, incomplete outcome data and selective reporting were also at a low risk (Fig. 2). Table 2 showed the results of quality assessments of five cohort studies. All studies were relatively high in quality with seven or more stars under NOS measurements.

### PSA progression

Four studies reported the PSA progression during the follow-up time. There was no heterogeneity among these four studies ( $I^2 = 0\%$ ,  $P = 0.54$ ), and no significant difference

**Figure 1** PRISMA flow diagram of study selection.

Full-size DOI: 10.7717/peerj.9282/fig-1

was found in PSA progression between 5ARI and control groups (OR = 0.82, 95% CI [0.52–1.29],  $P = 0.40$ ) (Fig. 3).

In the subgroup analyses based on previous therapy, PCa patients receiving previous RP/RT (OR = 0.76, 95% CI [0.47–1.23],  $P = 0.26$ ) or no treatments (OR = 1.56, 95% CI [0.39–6.16],  $P = 0.53$ ) did not show significant difference in PSA progression between 5ARI and control groups; and no patient with previous AS treatments were involved in this analysis. In addition, pooled results evaluating the tumor type also indicated no significant difference in all subgroups (local PCa: OR = 0.66, 95% CI [0.37–1.17],  $P = 0.16$ ; metastatic PCa: OR = 1.56, 95% CI [0.39–6.16],  $P = 0.53$ ; non-metastatic CRPC: OR = 1.06, 95% CI [0.44–2.53],  $P = 0.90$ ).

### Total progression

Total progression of PCa was detected in nine included studies, and no significant heterogeneity existed ( $I^2 = 20\%$ ,  $P = 0.26$ ). Results of meta-analysis revealed that 5ARI treatment significantly reduced the total progression of PCa (OR = 0.61, 95% CI [0.48–0.77],  $P < 0.0001$ ) (Fig. 4). No publication bias was discovered through either inverted funnel plot (Fig. 5) or Egger's test ( $t = -0.52$ ,  $P = 0.622$ ).

Full-size DOI: 10.7717/peerj.9282/fig-2

Table 3 showed the results of subgroup analyses for total progression. It seemed that the 5ARIs were effective in decreasing PCa progression regardless of patients' race, study design, previous therapy, and 5ARI type. However, in subgroups of tumor type and Gleason score, 5ARI treatment proved to be beneficial for patients with local PCa (OR = 0.56, 95% CI [0.44–0.73],  $P < 0.00001$ ) and low Gleason score ( $\leq 7$ ) (OR = 0.63, 95% CI [0.48–0.84],  $P = 0.002$ ).

### Progression-free survival

Multivariable adjusted HR of 5ARI treatment in predicting progression-free survival was available in five studies. Our results demonstrated 5ARIs could significantly prolonged the progression-free survival time in PCa patients (HR = 0.57, 95% CI [0.34–0.96],  $P = 0.04$ ), with moderate heterogeneity ( $I^2 = 69\%$ ,  $P = 0.01$ ) (Fig. 6). The inverted funnel plot did not find any publication bias. In the subgroup analyses based on previous therapy, however, no significant difference was found in neither PCa patients received previous

**Note:**

One ★ means one point in the Newcastle-Ottawa Scale scores.

**Figure 3** Comparison of PSA progression between prostate cancer patients with and without 5ARI treatment. [Full-size DOI: 10.7717/peerj.9282/fig-3](https://doi.org/10.7717/peerj.9282/fig-3)

RP/RT (OR = 0.40, 95% CI [0.14–1.14],  $P = 0.09$ ) nor AS (OR = 0.70, 95% CI [0.32–1.52],  $P = 0.36$ ) between 5ARIs and control groups. Similarly, no significant difference was found in subgroup analyses based on tumor type (local PCa: OR = 0.56, 95% CI [0.27–1.15],  $P = 0.11$ ; non-metastatic CRPC: OR = 0.62, 95% CI [0.36–1.07],  $P = 0.08$ ).

**Side-effects**

Three studies compared cases with side-effects between 5ARIs and control groups. No significant difference was found in the occurrence of side-effects between two groups (OR = 1.01, 95% CI [0.68–1.50],  $P = 0.95$ ) with no heterogeneity ( $I^2 = 0\%$ ,  $P = 1.00$ ) (Fig. 7). Publication bias was not reached from the inverted funnel plot.

**Figure 4** Comparison of total progression between prostate cancer patients with and without 5ARI treatment. [Full-size](#) DOI: 10.7717/peerj.9282/fig-4

**Figure 5** Funnel plot with pseudo 95% confidence limits of 5ARIs treatment and prostate cancer total progression. [Full-size](#) DOI: 10.7717/peerj.9282/fig-5

## Other outcomes

Table 4 provided summarized results of outcomes explored in less than three studies. No significant differences were found in PCa recurrence, metastasis, biopsy reclassification or partial treatment response between 5ARIs and control groups. However, 5ARIs were still found to be effective in improving the complete treatment response for PCa patients (OR = 71.13, 95% CI [4.01–1262.24],  $P = 0.004$ ).

## DISCUSSION

We concluded that 5ARIs decreased the total progression of PCa, especially for patients with local and low Gleason score ( $\leq 7$ ) PCa. 5ARIs also prolonged the progression-free survival time and increased the rate of complete therapy response. In addition, the use of 5ARIs did not bring more side-effects to PCa patients. Above all, 5ARIs benefited more

patients with local and low Gleason score ( $\leq 7$ ) PCa, especially in delaying the disease progression. [Luo et al. \(2019\)](#) reported a similar meta-analysis with us recently, however, they mainly focused on the impact of 5ARIs treatment on the incidence of PCa. Although only two studies were included to evaluate the effect of 5ARIs on PCa progression, their pooled results also supported our conclusions, indicating 5ARI treatment could delay the progression of low-risk prostate cancer ([Luo et al., 2019](#)).

Androgen receptor pathway plays an important role in prostate growth and progression of prostate diseases, including BPH and PCa. Dihydrotestosterone is converted from testosterone in prostate by  $5\alpha$ -reductase isozymes and is more potent than testosterone. This conversion can be inhibited by 5ARIs, which decreases the level of dihydrotestosterone ([McConnell et al., 1992](#)). Thus, 5ARIs have potential effects on treating PCa. Many studies demonstrated that the use of 5ARIs reduced the risk of PCa. [Preston et al. \(2014\)](#) reported that 5ARIs were associated with a decrease in the incidence of overall and Gleason score  $\leq 7$  PCa based on their subgroup analysis, and did not cause the development of high-grade or lethal PCa, but the number of patients in this cohort was relatively small. Results from long-term follow-up showed that although high-grade and non-localized PCas were more common in 5ARIs group, 5ARIs had no influences on the survival outcomes ([Murtola et al., 2016](#); [Thompson et al., 2013](#)). In general, the efficacy and safety of 5ARIs after PCa diagnosis is still unclear.

Many previous studies reported the association between 5ARIs and PCa. Dutasteride was proved to induce a dose-dependent apoptosis in androgen-sensitive human prostate cancer cells, but not in androgen-independent ones ([Maria McCrohan et al., 2006](#)). [Schmidt et al. \(2009\)](#) assessed the changes in gene expression in androgen-responsive xenograft tumors following dutasteride treatment. In their results, dutasteride significantly reduced the tumor size by affecting apoptosis, cytoskeletal remodeling, and cell cycle pathways. A series of studies by Wang and colleagues ([Gupta et al., 2010](#); [Masoodi et al., 2013](#); [Pascal et al., 2015](#)) suggested that inhibition of  $5\alpha$ -reductase enhanced the expression of U19/Eaf2, an androgen-regulated tumor suppressor, in LNCaP xenograft tumor during the treatment with testosterone replacement. 5ARIs can suppress the initial regrowth of regressed prostate tumors and testosterone-stimulated proliferation of LNCaP cells precultured in androgen-free media. They further used LNCaP xenograft tumor model to

evaluate the effectiveness of short off-cycles during intermittent androgen deprivation therapy coupled with 5ARIs. Their results confirmed this treatment could block tumor regrowth and improve patients' survival. *Xu et al. (2006)* reported that combination of dutasteride and castration had a greater tumor inhibition effect than castration monotherapy in androgen-responsive LNCaP cancers, but not in androgen-independent PC-3 human prostatic cancer xenografts. Another study pointed out dutasteride combined with anti-androgen drugs suppressed ERG fusion-positive prostate cancer cell growth and reduced the tumor burden (*Ateeq et al., 2012*). All the above studies demonstrated possible mechanisms and potential effects of PCa treated by 5ARIs.

The low-risk localized PCa is very common and it is tested more frequently under PSA screening (*Cooperberg et al., 2004*). *Kearns et al. (2019)* reported that continuous use of 5ARIs on patients who were enrolled in AS programs for PCa reduced the rate of RP or any other curative treatments, but did not influence the reclassification. Five included studies in our meta-analysis were performed among patients on AS. Our result indicated that 5ARIs reduced the progression and prolonged the progression-free survival time, especially in patients with local PCa or Gleason score  $\leq 7$ . It was suggested that these patients on AS benefited more from 5ARIs treatment.

Finasteride is a selective type 2  $5\alpha$ -reductase inhibitor, while dutasteride is a dual  $5\alpha$ -reductase inhibitor. Based on previous studies, the level of  $5\alpha$ -reductase type 2 was lower and type 1 was higher in PCa tissues compared with those in normal prostates (*Thomas et al., 2008; Xu et al., 2006*). Both types were elevated in high-grade PCa tissues compared with low-grade ones (*Thomas et al., 2008*). *Ateeq et al. (2012)* reported that type 1 and type 3  $5\alpha$ -reductase were expressed more in metastatic tumor tissues than in benign and local ones. Consequently, the reactivities to 5ARIs were different due to expression levels of  $5\alpha$ -reductase. It might be one of the reasons for various results in these studies. Further studies are still needed to determine how to identify PCa patients who will benefit from 5ARIs.

Some limitations also should be considered in this meta-analysis. First, due to very limited numbers of studies that focused on single topics such as single study design type, tumor type, 5ARI type and previous therapy, we had to combine these different types of studies together, which may bring heterogeneity and potential bias to our results. Thus, our results should be treated cautiously. Second, there was not enough data to conduct subgroup analyses on doses and treatment duration; what's more, the numbers of included studies in other subgroup analyses were also small. Third, the sample size of some studies was small, which may impact the quality of data analyses. Additionally, studies in languages other than English, with incomplete data, or not published, were excluded in our analysis, which may introduce the enrollment bias.

## CONCLUSIONS

Our study demonstrates that 5ARI treatment can benefit patients with local and low Gleason score ( $\leq 7$ ) PCa, especially in delaying the disease progression. More studies with larger sample size and comprehensive study design are still needed to further verify our outcomes.

## ADDITIONAL INFORMATION AND DECLARATIONS

### Funding

This study was financed by grants from the National Natural Science Foundation of China (No. 81802821), the Natural Science Foundation of Guangdong Province (No. 2017A030310547), and the China Postdoctoral Science Foundation (Nos. 32018T110859 and 2017M612636). The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

### Grant Disclosures

The following grant information was disclosed by the authors:

National Natural Science Foundation of China: 81802821.

Natural Science Foundation of Guangdong Province: 2017A030310547.

China Postdoctoral Science Foundation: 2018T110859 and 2017M612636.

### Competing Interests

The authors declare that they have no competing interests.

### Author Contributions

- Tuo Deng conceived and designed the experiments, performed the experiments, analyzed the data, prepared figures and/or tables, authored or reviewed drafts of the paper, and approved the final draft.
- Xueming Lin performed the experiments, analyzed the data, prepared figures and/or tables, authored or reviewed drafts of the paper, and approved the final draft.

- Xiaolu Duan performed the experiments, prepared figures and/or tables, authored or reviewed drafts of the paper, and approved the final draft.
- Zihao He analyzed the data, authored or reviewed drafts of the paper, and approved the final draft.
- Zhijian Zhao analyzed the data, authored or reviewed drafts of the paper, and approved the final draft.
- Guohua Zeng conceived and designed the experiments, authored or reviewed drafts of the paper, and approved the final draft.

### Data Availability

The following information was supplied regarding data availability:

All data generated or analyzed in this study are available in the “Results”, [Tables 1–4](#) and [Figs. 1–7](#).

### Supplemental Information

Supplemental information for this article can be found online at <http://dx.doi.org/10.7717/peerj.9282#supplemental-information>.
