# Crystal structure of (2-acetylferrocen-1-yl)boronic acid

Andrea Preuss, Marcus Korb and Heinrich Lang\*

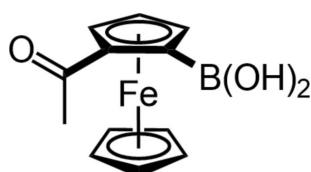

Technische Universität Chemnitz, Faculty of Natural Sciences, Institute of Chemistry, Inorganic Chemistry, D-09107 Chemnitz, Germany. \*Correspondence e-mail: heinrich.lang@chemie.tu-chemnitz.de

(2-Acetylferrocen-1-yl)boronic acid,  $[\text{Fe}(\text{C}_5\text{H}_5)(\text{C}_7\text{H}_8\text{BO}_3)]$  or  $2\text{-C}(\text{O})\text{CH}_3\text{-1-B(OH)}_2\text{-Fc}$  [ $\text{Fc} = \text{Fe}(\eta^5\text{-C}_5\text{H}_3)(\eta^5\text{-C}_5\text{H}_5)$ ], crystallizes in the centrosymmetric space group  $P2_1/n$ . The boronic acid functionality interacts *via* intramolecular hydrogen bonds with the acetyl group and with the  $-\text{B}(\text{OH})_2$  functionality of an adjacent molecule. The resulting centrosymmetric dimer exhibits an *anti*-positioning of the ferrocenyl moieties towards the central  $\text{B}_2\text{O}_4$  plane. Consequently, an  $(R_p,S_p)$ -*i.e.* a *meso* configuration is present for this dimer. In the crystal, weak C—H···O hydrogen bonds consolidate the molecular packing.

## 1. Chemical context

The synthesis of 1,2-functionalized ferrocenes is a striking topic in ferrocene chemistry (Schaarschmidt & Lang, 2013; Korb *et al.*, 2014a) and is mostly realized *via* *ortho*-directed metalation and subsequent reaction with electrophiles (Schaarschmidt & Lang, 2013) or intramolecular rearrangement (Werner & Butenschön, 2013; Korb & Lang, 2014, 2016; Korb *et al.*, 2017). The resulting ferrocenes are predominantly used as ligands in *C,C* cross-coupling catalysis (Schaarschmidt *et al.*, 2014; Jensen & Johannsen, 2003; Vinci *et al.*, 2009; Debono *et al.*, 2010; Karpus *et al.*, 2016), but also the introduction of ferrocenyl substituents by catalytic conversions is of rising interest (Hildebrandt *et al.*, 2011*a,b*; Speck *et al.*, 2015; Korb *et al.*, 2014*b*). The introduction of electronically and sterically modified substrates requires the synthesis of the respective ferrocenes that bear groups suitable for oxidative additions or transmetalation reactions (Lehrich *et al.*, 2015; Speck *et al.*, 2014). In case of substrates that are sensitive towards a nucleophilic attack, *e.g.* acyl groups, the Suzuki–Miyaura instead of a Negishi reaction is commonly used, and hence requires the presence of a boronic acid functionality (Speck *et al.*, 2015). However, the acidic protons prevent a straightforward *ortho*-directed metalation, and additional reaction steps for the introduction and removal of protecting groups are required. Electrophilic aromatic substitution ( $S_{\text{EAr}}$ ) reactions are also not suitable, since they usually give 1'- or 3-functionalized products (Rosenblum & Woodward, 1958).

Within our attempts to synthesize new electronically modified ferrocenes as substrates for Suzuki–Miyaura reactions, we herein present the synthesis and crystal structure of an *ortho*-functionalized ferrocenylboronic acid, obtained *via*  $S_{\text{EAr}}$  without using a protection group strategy for the acidic protons.

## 2. Structural commentary

The title compound crystallizes in the centrosymmetric space group  $P2_1/n$  with one molecule in the asymmetric unit (Fig. 1). An intramolecular hydrogen bond between the oxygen atom of the acetyl group (O1) and the neighbouring hydroxy group (O2) of the boronic acid functionality of 2.650 (2) Å (Table 1) is present. Therefore, both substituents are co-planar with each other [ $\text{BO}_2 \cdots \text{C}_2\text{O} = 2.9 (4)^\circ$ ]. The C=O distance of 1.233 (2) Å is neither affected by the involvement into this hydrogen bond, nor the presence of an *ortho* substituent and is therefore similar to unsubstituted acetyl ferrocene (Sato *et al.*, 1984).

With regard to the  $C_5H_3$  plane of the ferrocenyl backbone, both substituents reveal a slight *endo*-bending of 7.0 (3)° ( $C_5H_3 \cdots C_2\text{O}$ ) and 9.5 (3)° ( $C_5H_3 \cdots BO_2$ ). The ferrocenyl backbone exhibits an eclipsed conformation ( $C1-Cg-Cg-C8 = 8.21 (14)^\circ$ ;  $Cg$  is the centroid of the respective cyclopentadienyl ring) and a tilt angle of 179.28 (2)°. The hydrogen atom at O3 is directed away from the ferrocenyl backbone and points to an adjacent molecule.

## 3. Supramolecular features

In addition to the aforementioned intramolecular hydrogen bond between O1 and O2, the latter atom is also involved as an acceptor of an intermolecular hydrogen bond with the second hydroxy group (O3) of an adjacent boronic acid

**Table 1**  
Hydrogen-bond geometry (Å, °).

$D-\text{H}\cdots A$	$D-\text{H}$	$\text{H}\cdots A$	$D\cdots A$	$D-\text{H}\cdots A$
O2—H2O···O1	0.82	1.85	2.650 (2)	166
O3—H3O···O2 <sup>i</sup>	0.82	1.94	2.744 (2)	168
C9—H9···O3 <sup>ii</sup>	0.93	2.45	3.308 (3)	154
C10—H10···O1 <sup>iii</sup>	0.93	2.53	3.404 (3)	156

Symmetry codes: (i)  $-x + 1, -y + 1, -z + 1$ ; (ii)  $x - 1, y, z$ ; (iii)  $x - \frac{1}{2}, -y + \frac{3}{2}, z - \frac{1}{2}$ .

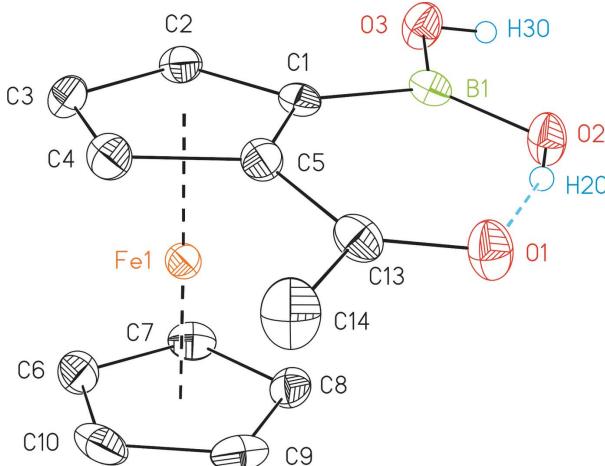

functionality of 2.744 (2) Å (Fig. 2, Table 1). The resulting dimer is centrosymmetric with the inversion center located at the middle of the eight-membered ring formed by the two boronic acid functionalities. Therefore, both ferrocenyl moieties are positioned *anti* with regard to the central  $\text{B}_2\text{O}_4$  plane. Hence, a racemic mixture of both enantiomers crystallized, giving the  $R_p/S_p$ -configured, *i.e.* *meso* diastereomer if the dimer is considered as one supramolecular entity. The respective *racem* configuration ( $R_p/R_p$  or  $S_p/S_p$ ) is not present within the packing (Fig. 3).

The B—O bond lengths involving O3 [1.356 (3) Å] and O2 [1.362 (3) Å] are similar, although the latter also acts as a hydrogen-bond acceptor, in contrast to O3.

A short contact of 4.6807 (14) Å between a  $C_5H_3$  and a  $C_5H_5$  ring does not show a perpendicular positioning of the two groups ( $\beta = 25^\circ$ ) and therefore does not fit the criteria for a *T*-shaped  $\pi\cdots\pi$  interaction (Sinnokrot *et al.*, 2002). However, weak C—H···O interactions between aromatic H atoms and the carbonyl O1 atom and a boronic acid O atom (O3) consolidate the crystal packing (Table 1).

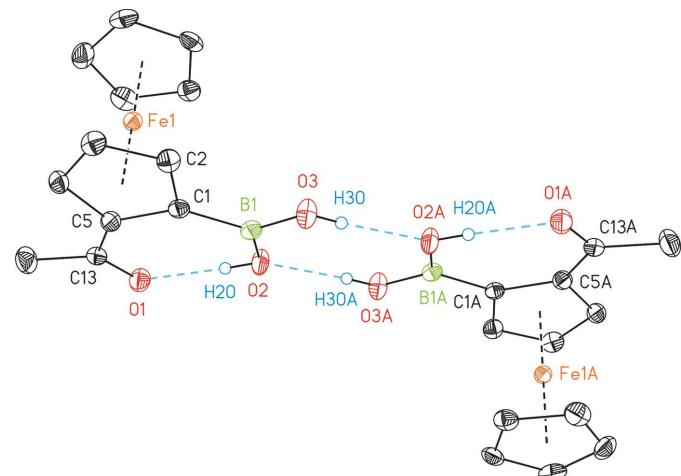

## 4. Database survey

Besides ferrocenyl boronic acid (Bresner *et al.*, 2004) and acetyl ferrocene (Sato *et al.*, 1984) that are frequently used in

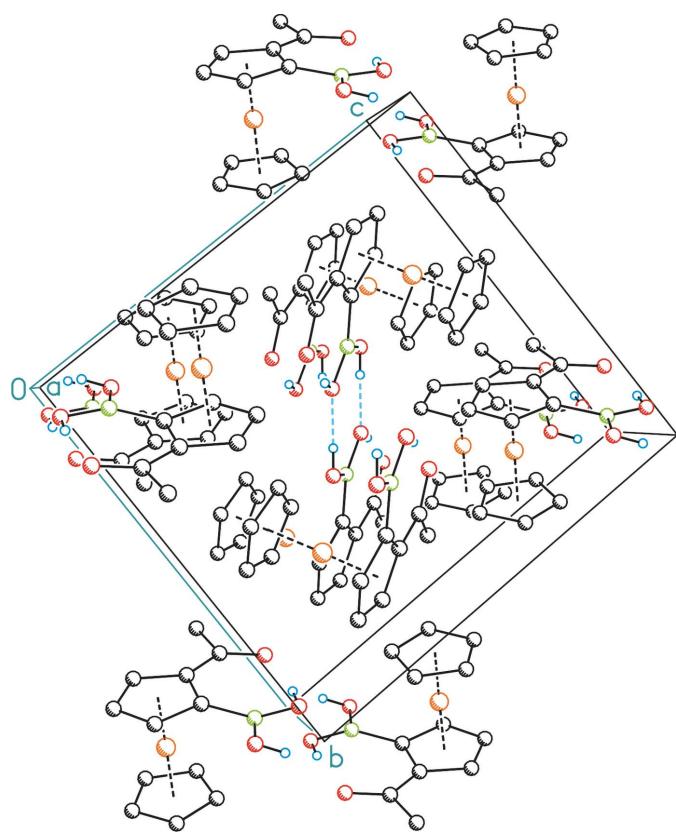

**Figure 1**

The molecular structure of the title compound showing the intramolecular hydrogen bond between the acetyl and the boronic acid functionalities. Displacement ellipsoids are drawn at the 50% probability level; C-bonded hydrogen atoms have been omitted for clarity.

**Figure 2**

Intra- and intermolecular hydrogen bonds within the dimer, with displacement ellipsoids drawn at the 50% probability level. C-bonded hydrogen atoms have been omitted for clarity. [Symmetry code: (A)  $1 - x, 1 - y, 1 - z$ .]

**Figure 3**

Unit cell of the title compound in a view along [100]. Hydrogen bonds are shown as pale-blue dashed lines; displacement ellipsoids are drawn at the 50% probability level. C-bonded hydrogen atoms have been omitted for clarity.

general, other *ortho*-substituted analogues are sparsely described.

Crystal structures of acetylferrocenes bearing additional *ortho*-substituents are limited to a few examples, *e.g.* with  $\text{PPh}_2$  (Torres *et al.*, 2011), iodine (Ferber *et al.*, 2007) and a ferrocenylmethyl group (Xie *et al.*, 2011) as the sole second substituent. In contrast, carbonyl, *i.e.* formyl or acyl groups, are more common, *e.g.* in ferrocenoyl methylferrocene (Enders *et al.*, 2003).

Functionalized ferrocenylboronic acids are usually reported together with their protected 1,3,2-dioxaborolane derivatives. As *ortho*-substituents, diisopropylcarbamoyl (Batsanov *et al.*, 2007) and dimethylcarbamoyl (Norrid & Søtofte, 2001), together with their respective aminomethyl derivatives (Batsanov *et al.*, 2007; Norrid & Søtofte, 2001) have structurally been described. Heterocycles, such as imidazolidone (Metallinos *et al.*, 2012) are also known as *ortho*-substituents for ferrocenyl derivatives.

In case of non-ferrocenyl-based aromatics, the  $2\text{-C(O)CH}_3\text{-}1\text{-B(OH)}_2$  substitution pattern is solely reported for the benzene core (Ganguly *et al.*, 2003). In contrast to the title compound, the boronic acid functionality is rotated out of coplanarity with the benzene core and the acetyl group by 78.2 and 77.7°, respectively.

**Table 2**

Computer programs: *CrysAlis CCD* and *CrysAlis RED* (Oxford Diffraction, 2014), *SHELXT2013* (Sheldrick, 2015a), *SHELXL2013* (Sheldrick, 2015b), *ORTEP-3 for Windows* and *WinGX* (Farrugia, 2012), *SHELXTL* (Sheldrick, 2008) and *publCIF* (Westrip, 2010).

For *ortho*-carbonyl groups in general, the involvement of the boronic acid functionality in inter- and intramolecular hydrogen bonds, similar to the title compound, is a common feature (Yan *et al.*, 2003; Luliński *et al.*, 2007; Durka *et al.*, 2014; Madura *et al.*, 2015).

## 5. Synthesis and crystallization

Ferroceneboronic acid (0.5 g, 2.175 mmol) was suspended in acetic anhydride (10 ml). To this suspension  $\text{BF}_3\cdot\text{OEt}_2$  (0.40 ml, 3.15 mmol) was added in a single portion. The reaction mixture was stirred for 30 min at ambient temperature. Afterwards, the mixture was poured into ice and was stirred for 10 minutes. A KOH solution (9 M, 10 ml) was added in a single portion following a neutralization with  $\text{K}_2\text{CO}_3$  until the  $\text{CO}_2$  evolution stopped. The mixture was extracted with dichloromethane ( $3\times 20$  ml) and the organic phase was dried over  $\text{MgSO}_4$ . The volatiles were removed in vacuum (1 mbar). The crude material obtained was purified by flash chromatography on silica using a 4/1 (*v/v*) diethyl ether/dichloromethane mixture. The title compound was isolated as a brown solid. Yield: 75 mg (0.28 mmol, 13% based on ferroceneboronic acid).

IR data (KBr,  $\nu/\text{cm}^{-1}$ ): 3357 (*w*), 2925 (*m*), 2855 (*m*), 1685 (*m*), 1654 (*s*), 1647 (*m*), 1636 (*s*), 1618 (*s*), 1578 (*m*), 1559 (*m*), 1522 (*m*), 1507 (*m*), 1457 (*s*); 1419 (*s*), 1411 (*s*), 1374 (*s*), 1354 (*s*), 1345 (*s*); 1318 (*m*), 1247 (*m*), 1207 (*m*), 1134 (*m*), 1106 (*m*), 1094 (*m*), 1045 (*m*), 1001 (*w*), 924 (*w*), 873 (*w*), 862 (*w*), 785

HRMS (ESI-TOF,  $m/z$ ) calculated for  $\text{C}_{12}\text{H}_{13}\text{BFeO}_3$  272.0304, found 272.0320 [ $M]^+$ .

Crystals suitable for X-ray crystallography were obtained from evaporation of a saturated dichloromethane solution at ambient temperature.

## 6. Refinement

Crystal data, data collection and structure refinement detail are summarized in Table 2. C-bound H atoms were placed in calculated positions and constrained to ride on their parent atoms with  $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$  and a C—H distance of 0.93 Å for aromatic and  $U_{\text{iso}}(\text{H}) = 1.5U_{\text{eq}}(\text{C})$  and a C—H distance of 0.96 Å for methyl H atoms, with their torsion angle derived from the residual electron density. The hydroxy hydrogen atoms were located from difference-Fourier maps but were treated with idealized geometry with  $U_{\text{iso}}(\text{H}) = 1.5U_{\text{eq}}(\text{O})$ , an O—H distance of 0.82 Å and a torsion angle derived from the residual electron density.

*Special details*

**Geometry.** All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted R factor wR and goodness of fit S are based on  $F^2$ , conventional R factors R are based on F, with F set to zero for negative  $F^2$ . The threshold expression of  $F^2 > 2\sigma(F^2)$  is used only for calculating R factors(gt) etc. and is not relevant to the choice of reflections for refinement. R factors based on  $F^2$  are statistically about twice as large as those based on F, and R factors based on ALL data will be even larger.
