ABSTRACT

The interconversion of hexose-6-phosphate and hexose-1-phosphate can be directly analyzed by high-performance anion-exchange chromatography coupled with an electrochemical detector (HPAEC-PAD). Thus, this method can be used to measure the activities of N-acetylglucosamine-phosphate mutase (AGM), glucosamine-phosphate mutase (GlmM) and phosphoglucosmutase (PGM), which are the members of α -D-phosphohexomutases superfamily. The detection limits were extremely low as 2.747 pmol, 1.365 pmol, 0.512 pmol, 0.415 pmol, 1.486 pmol and 0.868 pmol for N-acetylglucosamine-1-phosphate (GlcNAc-1-P), N-acetylglucosamine-6-phosphate (GlcNAc-6-P), glucosamine-1-phosphate (GlcN-1-P), glucosamine-6-phosphate (GlcN-6-P), glucose-1-phosphate (Glc-1-P) and glucose-6-phosphate (Glc-6-P), respectively. By employing HPAEC-PAD, activities of *At*AGM (AGM from *Arabidopsis thaliana*) on these six phosphohexoses can be detected. The K_m of *At*AGM on Glc-1-P determined by HPAEC-PAD was $679.18 \pm 156.40 \mu\text{M}$, which is comparable with the K_m of $707.09 \pm 170.36 \mu\text{M}$ detected by traditional coupled assay. Moreover, the activity of *Mt*GlmM (GlmM from *Mycobacterium tuberculosis*) on GlcN-6-P tested by HPAEC-PAD was $7493.40 \pm 309.12 \text{ nmol/min} \cdot \text{mg}$, which is much higher than $288.97 \pm 35.28 \text{ nmol/min} \cdot \text{mg}$ obtained by the traditional coupled assay. Accordingly, HPAEC-PAD is a more rapid and simple method than the traditional coupled assays given its high specificity and sensitivity, and will certainly bring convenience to further research of α -D-phosphohexomutases.

INTRODUCTION

N-acetylglucosamine (GlcNAc) is an essential sugar involved in various cellular processes. Generally, uridine di-phosphate (UDP)-GlcNAc is the active form of GlcNAc *in vivo*, and synthesized in a four-step cytoplasmic biosynthesis pathway, which is known as hexosamine pathway (Milewski, Gabriel & Olchow, 2006; Piacente et al., 2014). The

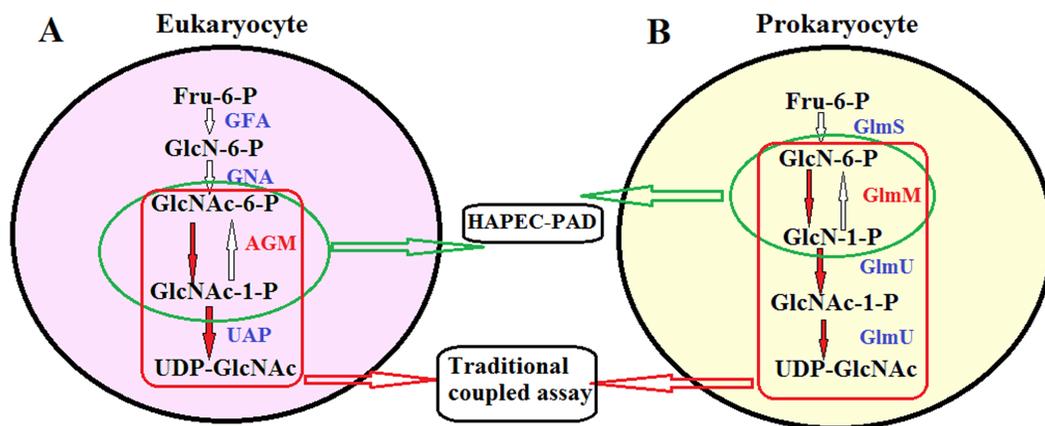

Figure 1 The hexosamine pathway in eukaryocyte and prokaryocyte. (A) The pathway in eukaryocyte was catalyzed by GlcN-6-P synthase (GFA), GlcN-6-P acetyltransferase (GNA), N-acetylglucosamine-phosphate mutase (AGM) and UDP-GlcNAc pyrophosphorylase (UAP) respectively. (B) The pathway in prokaryocyte was catalyzed by glutamine fructose-6-phosphate transferase (GlmS), phosphoglucosamine mutase (GlmM), glucosamine-1-phosphate acetyltransferase/N-acetylglucosamine-1-phosphate uridylyltransferase (GlmU) respectively. The activity of AGM and GlmM could be detected by HAPEC-PAD method or traditional coupled assay.

hexosamine pathway is a branch of glycolysis. It is associated with posttranslational protein modification by glycosylation and involved in the synthesis of glycolipids, proteoglycans, and glycosylphosphatidylinositol anchors (Vosseller *et al.*, 2002; Wells, Vosseller & Hart, 2001; Zachara & Hart, 2004). The hexosamine pathway is a survival feature of neoplastic cells, plays a prominent role during tumourigenesis, and can be exploited therapeutically to target cancer cells (Vasseur & Manie, 2015). The hexosamine pathway is also essential for the growth of pathogenic bacteria, and can be used as a potential excellent target for anti-bacteria drugs (Li *et al.*, 2012).

In living organisms, there are three variations of hexosamine pathway according to the different reaction sequence and enzymes, which are eukaryotic (Fig. 1A), prokaryotes (Fig. 1B) and mimivirus pathways (Piacente *et al.*, 2014). The hexosamine pathway in mimivirus follows the eukaryotic-like strategy, but also shares some properties with prokaryotic pathway (Piacente *et al.*, 2014). The enzymes in hexosamine pathway have been well studied except N-acetylglucosamine-phosphate mutase (AGM) and glucosamine-phosphate mutase (GlmM) (Fang *et al.*, 2013; Milewski, Gabriel & Olchoway, 2006). The main reason is the limitation of methodology on α -D-phosphohexomutases activity.

AGM, GlmM and phosphoglucomutase (PGM) all belong to the α -D-phosphohexomutases superfamily (Shackelford, Regni & Beamer, 2004). Despite the differences in substrate specificity, the catalytic properties in this superfamily are nearly the same. They catalyze the reversible conversion of hexose-6-P to hexose-1-P via a bisphosphorylated sugar intermediate. Active enzyme is phosphorylated at a conserved serine residue and binds one Mg^{2+} ion (Shackelford, Regni & Beamer, 2004). Reversible conversion of hexose-1-P to hexose-6-P is difficult to be detected by a conventional method.

Traditionally, the activity of α -D-phosphohexomutase was determined by a coupled enzyme system. PGM catalyze the interconversion of glucose-1-phosphate (Glc-1-P) and Glc-6-P. The normal way to detect the activity of PGM was using Glc-1-P as substrates, glucose-6-phosphate dehydrogenase (G6PDH) as coupled enzyme, by detect the increasing absorbance values of NADH at 340 nm (Nishinari *et al.*, 2012; Wang & Zhang, 2010). This method was convenience and simple because G6PDH was commercially available and cost-effective. However, the detection of the reverse reaction which uses Glc-6-P as a substrate is still impossible.

GlcNAc-6-P was always used as a substrate for detecting the AGM activity, and GlcNAc-1-P uridylyltransferase (UAP), the fourth enzyme in hexosamine pathway, was used as a coupled enzyme (Boles *et al.*, 1994; Greig *et al.*, 2007; Jolly *et al.*, 2000) (Fig. 1A). The detection of GlmM activity was carried out by using GlcN-6-P as substrate, and coupled with the third and fourth enzyme GlmU (Li *et al.*, 2012; Li *et al.*, 2011) (Fig. 1B). However, this coupled method was very complex and tedious, and especially UAP and GlmU were commercial unavailable. Furthermore, the most noticeable limitation of the traditional coupled assay is impossible to detect the reverse reaction, which using GlcNAc-1-P or GlcN-1-P as substrate.

In order to overcome the limitations of the traditional coupled assay on the determination of the activity of α -D-phosphohexomutases, a simple and convenient method which can detect the interconversion of hexose-6-P and hexose-1-P directly is urgently needed.

High-performance anion-exchange chromatography (HPAEC) has been used for the quantitation of carbohydrates (Kazłowski, Pan & Ko, 2015; Yang, Hsieh & Lin, 2015) because its strong anion-exchange property allows the highly selective separation of carbohydrates. It has been tried to detect and separate the phosphohexoses directly by HPAEC for decades. In previous studies, Jolly *et al.* (1999) detected glucosamine phosphates by HPAEC with a post-column derivatization. detected glucose phosphates by HPAEC with ^{14}C labeled method. Naught & Tipton, (2005). However, they all needed radiochemical detector or fluorescence detector, and the phosphohexoses pretreatment were complex and expensive. Recently, several phosphohexoses had been successfully separated by HPAEC (Jeong *et al.*, 2007; Marcellin *et al.*, 2009), but the separation of GlcNAc-1-P and GlcNAc-6-P is still unsuccessful. And also, there is no simple and convenient way to determine the activity of α -D-phosphohexomutases directly.

In this study, we developed a method by using HPAEC-PAD to separate phosphohexoses, which can be helpful to determine α -D-phosphohexomutases activity, especially AGM. Considering that AGM also has the ability to convert other phosphohexose (Boles *et al.*, 1994; Fang *et al.*, 2013; Greig *et al.*, 2007; Hofmann, Boles & Zimmermann, 1994), the interconversion of GlcNAc-6-P and GlcNAc-1-P, Glc-6-P and Glc-1-P, as well as GlcN-6-P and GlcN-1-P was investigated. In our knowledge, this is the first report to detect the AGM activity directly. This method also can be used to determine the activities of GlmM and PGM, which convert the interconversion of GlcN-6-P and GlcN-1-P, Glc-6-P and Glc-1-P.

MATERIALS AND METHODS

Materials

Glc-1-P, Glc-6-P, glucose-1,6-bisphosphate (Glc-1,6-2P) and GlcN-6-P were purchased from Sigma-Aldrich. GlcNAc-6-P, GlcNAc-1-P and GlcN-1-P were purchased from Santa Cruz Biotechnology. Double distilled water was used for HPLC, and all other solvents and chemicals were HPLC grade.

Chromatography

The HPAEC system consists of a Dionex Bio-LC gradient pump with GM-3 (4 mm) gradient mixer, CarboPac PA-100 column (4 × 250 mm), and an electrochemical detector with AgCl as reference electrode. The waveform was carbohydrates (standard Quad), the following pulse potentials were used for detection: $t = 0$ s, $E = 0.10$ v; $t = 0.20$ s, $E = 0.10$ v; $t = 0.40$ s, $E = 0.10$ v; $t = 0.41$ s, $E = -2.00$ v; $t = 0.42$ s, $E = -2.00$ v; $t = 0.43$ s, $E = 0.60$ v; $t = 0.44$ s, $E = -0.10$ v; $t = 0.50$ s, $E = -0.10$ v. The sample injection volume is 20 μ L and column oven temperature is maintained at 30 °C.

Elute conditions

The phosphohexoses should be eluted after 10 min because there were several interference peaks in the enzyme reaction mixture before 10 min on chromatograms. Thus, high pH elution was carried out in 100 mM sodium hydroxide under gradient conditions using a 80–720 mM sodium acetate gradient over 20 min at a flow rate of 0.5 ml/min.

The details of gradient conditions were 0–5 min, 80 mM sodium acetate; 5–15 min, 80–720 mM sodium acetate; 15–18 min, 720 mM sodium acetate; 18–20 min, 80 mM sodium acetate in 100 mM sodium hydroxide, 0.5 ml/min.

Expression and purification of AtAGM and MtGlmM

E. coli cells (*AtAGM::Amp*) were grown exponentially at 37 °C in LB medium with Amp. When the optical density (OD) of the culture reached 0.8, IPTG was added at a final concentration of 1 mM, and growth was continued for 12 h at 16 °C. Harvested cells were disrupted by sonication, centrifugated at 20,000 g for 30 min; the resulting supernatant was loaded onto Ni-NTA column (Qiagen, Hilden, Germany) for purification.

MtGlmM and *MtGlmU* were expressed and purified according to our previous studies ([Li et al., 2012](#); [Li et al., 2011](#)).

AtAGM assay

The activities of *AtAGM* (N-acetylglucosamine-phosphate mutase, from *Arabidopsis thaliana*) on different phosphohexoses, were tested in the same reaction mixture as described below. 154.80 pmol (10 μ g) *AtAGM* or boiled enzymes, were incubated in a substrate buffer (300 μ l) consisting of 20 mM PBS, pH 7.0, 10 mM MgSO₄, and 20 μ M Glc-1,6-2P and 0.1 mM different phosphohexose (GlcNAc-1-P, GlcNAc-6-P, GlcN-1-P, GlcN-6-P, Glc-1-P, Glc-6-P) ([Fang et al., 2013](#); [Hofmann, Boles & Zimmermann, 1994](#)) for 30 min at 30 °C. The reaction was terminated in boiling water and 200 μ l of 0.2 M NaOH were added for HPAEC-PAD analysis.

The Steady-state kinetics of *AtAGM* was analyzed by two methods using Glc-1-P as substrates. The HPAEC-PAD method was carried out by using 56.66 pmol *AtAGM* or boiled enzymes, incubated for 10 min at 30 °C in a substrate buffer as described above, with varying concentrations of Glc-1-P (60–8,000 μM). Then, the assay was terminated immediately in boiling water and 200 μl of 0.2 M NaOH were added for HPAEC-PAD analysis.

The traditional coupled assay was carried out in a 200 μl reaction volume containing 20 mM PBS, pH 7.0, 10 mM MgSO₄, 20 μM Glc-1,6-2P, a range of concentrations of Glc-1P (60–7,000 μM), 1 mM NAD⁺ and 2 units of G6PDH (*Anasontzis et al., 2014; Fang et al., 2013; Kim et al., 2014*). The reaction was started by the addition of 56.66 pmol *AtAGM* and incubated for 10 min at 30 °C. The amount of NADH produced was measured using a micro plate reader at 340 nm (BioTek, Gene 5).

All the experiments had repeated three times, and the K_m and V_{max} values were calculated by Origin 7.5.

MtGlmM assay

MtGlmM (glucosamine-phosphate mutase, from *Mycobacterium tuberculosis*) activity was determined by two methods.

The traditional coupled assay was conducted in a coupled enzyme system with *MtGlmU*, the third- and forth-step enzymes in hexosamine pathway in *Mycobacterium tuberculosis* (*Li et al., 2011*) (Fig. 1B). The GlcN-1-P converted from GlcN-6-P by the mutase was quantitatively converted into UDP-GlcNAc in the presence of purified *MtGlmU* in this coupled assay (*Li et al., 2012*) (Fig. 1B). The 50 μl reaction mixture contained 50 mM Tris-HCl, pH 8.0, 2.5 mM MgCl₂, 1 mM GlcN-6-P, 0.6 mM acetyl-CoA, 0.2 mM Glc-1,6-2P, purified *MtGlmU* (3.5 μg) and purified *MtGlmM* (0.18 μg). The reaction was incubated at 37 °C for 20 min and terminated by adding 50 μl of stop solution containing 50 mM Tris-HCl, pH 7.5, 6 M guanidine hydrochloride. The mixture was then incubated for 10 min by the addition of 50 μl of Ellman's reagent solution containing 0.2 mM DTNB in the buffer with 50 mM Tris-HCl, pH 7.5, and 1 mM EDTA. TNB, the product generated from the reaction of CoA-SH and DTNB, was monitored at 405 nm by Benchmark Plus plate reader (Thermo Fisher Scientific, Waltham, MA, USA).

MtGlmM activity was analyzed using HPAEC-PAD by detecting the interconversion of GlcN-6-P and GlcN-1-P directly. The purified *MtGlmM* (0.18 μg) was incubated at 37 °C for 20 min in a substrate buffer (50 μl) consisting of 1 mM GlcN-6-P (or GlcN-1-P) as substrate with 50 mM Tris-HCl, pH 8.0, 2.5 mM MgSO₄, and 0.2 mM Glc-1,6-2P. The reaction was terminated immediately in boiling water and 500 μl of 0.2 M NaOH were added for HPAEC-PAD analysis.

RESULTS AND DISCUSSION

The separation of standards

Under the elute conditions described in 'Materials and Methods', the retention times of GlcNAc-1-P, GlcNAc-6-P, GlcN-1-P, GlcN-6-P, Glc-1-P and Glc-6-P were 12.17 min,

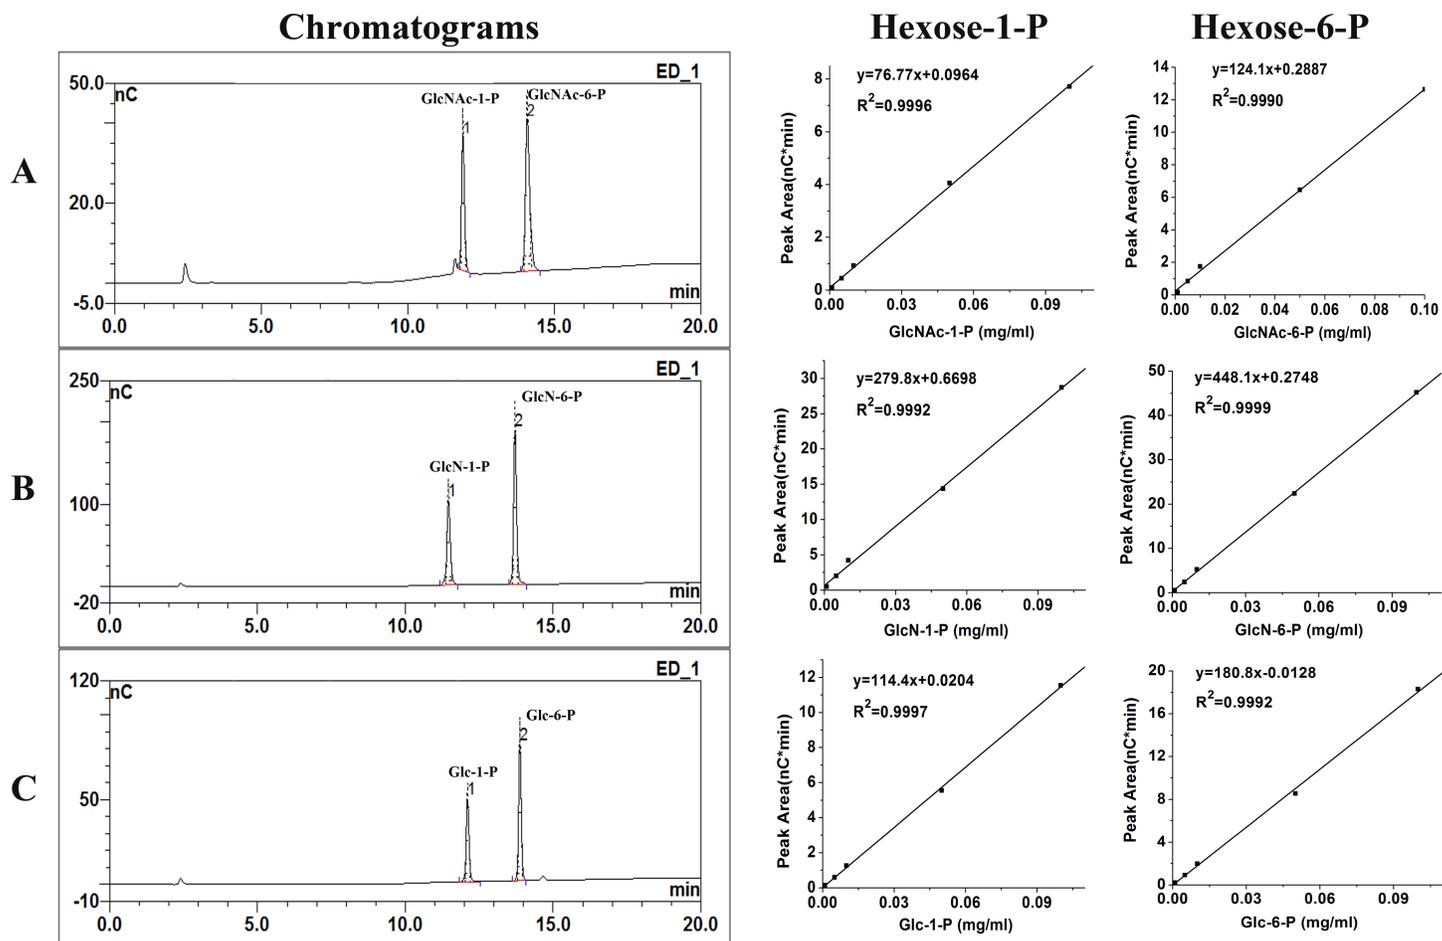

Figure 2 Chromatograms of calibration standards and their standard curves. Under the 80–720 mM sodium acetate gradient over 20 min at a flow rate of 0.5 ml/min, the calibration standards of 0.05 mg/ml GlcNAc-1-P, GlcNAc-6-P (A); 0.05 mg/ml GlcN-1-P, GlcN-6-P (B); 0.05 mg/ml Glc-1-P, Glc-6-P (C) were separated excellent on HPAEC-PAD chromatograms. Their standard curves were shown behind their chromatograms respectively; “nC” means PAD response.

14.30 min, 11.55 min, 13.75 min, 12.05 min and 13.72 min, respectively (Figs. 2A–2C). Hexose-1-P and hexose-6-P were separated excellent by HPAEC-PAD.

The detection limits are different for different phosphohexoses. The detection limits were 2.747 pmol, 1.365 pmol, 0.512 pmol, 0.415 pmol, 1.486 pmol and 0.868 pmol for GlcNAc-1-P, GlcNAc-6-P, GlcN-1-P, GlcN-6-P, Glc-1-P and Glc-6-P, respectively. The linearity of all the phosphohexoses was excellent (2–400 μM , $R^2 > 0.999$) as shown in Fig. 2. And HPAEC-PAD response was linearity in the range of concentration 1–15,000 μM ($R^2 > 0.99$).

Therefore, HPAEC-PAD method can be used to identify phosphohexose and determine the activity of α -D-phosphohexomutases by detecting the substrate consuming and product increasing at the same time.

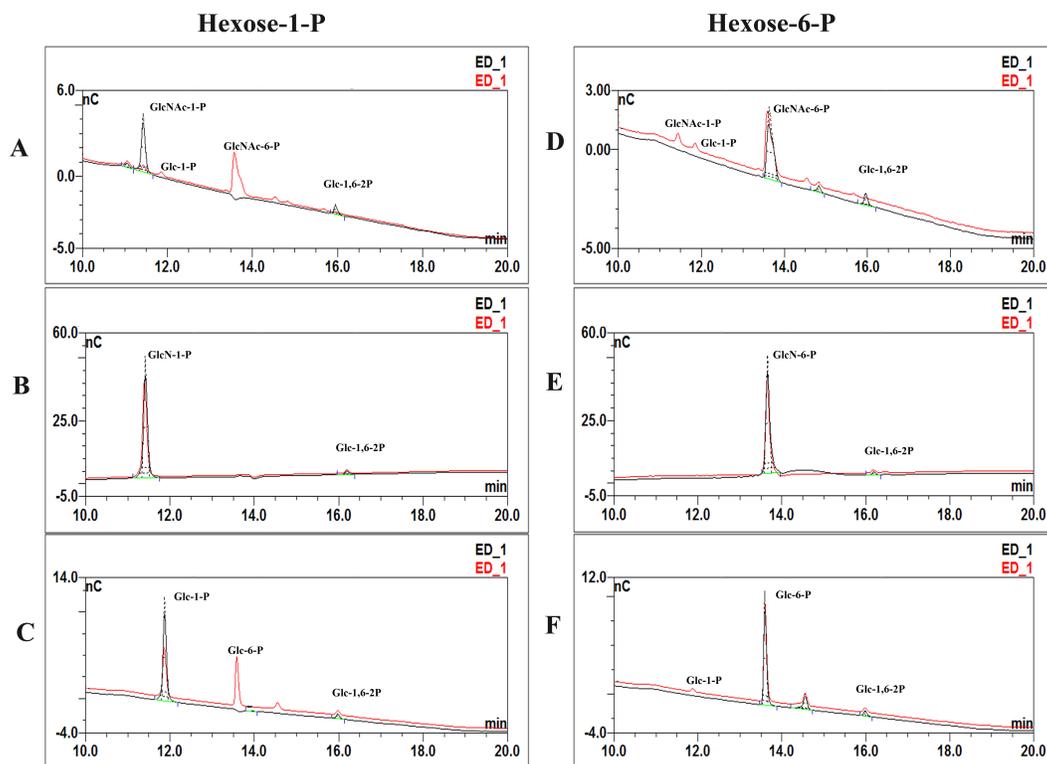

Figure 3 *AtAGM* activity on different substrates was assayed by HPAEC-PAD method. 154.80 pmol *AtAGM* or boiled enzymes, were incubated for 30 min at 30 °C in a substrate buffer (300 μ l) consisting of 20 mM PBS, pH 7.0, 10 mM MgSO₄, and 20 μ M glucose-1,6-bisphosphate (Glc-1,6-2P). And using GlcNAc-1-P (A), GlcN-1-P (B), Glc-1-P (C), GlcNAc-6-P (D), GlcN-6-P (E), and Glc-6-P (F) as substrate respectively (the final concentration is 0.1 mM). The black or red lines means the mixture after reaction, incubated with the boiled enzyme or *AtAGM*, respectively; “nC” means PAD response.

AGM assay

The chromatograms of the reaction mixtures of *AtAGM* incubated with different substrates (GlcNAc-1-P, GlcNAc-6-P, GlcN-1-P, GlcN-6-P, Glc-1-P and Glc-6-P) were shown in Fig. 3, including the chromatograms before (incubated with boiled enzyme) and after the reaction. The consuming of substrates and the producing of the products could be observed well in the chromatograms. The results showed that *AtAGM* indeed had the ability to convert these six phosphohexoses.

In order to identify the effectiveness of this novel method, both traditional coupled assay and HPAEC-PAD method were used to detect the steady-state kinetics and kinetic parameters of *AtAGM*. The activity of *Aspergillus fumigates* AGM on Glc-1-P determined by traditional coupled assay from Fang *et al.* (2013) was also taken as a comparison. The Steady-state kinetics and kinetic parameters of *AtAGM* were shown in Fig. 4 and Table 1. The K_m of *AtAGM* detected by HPAEC-PAD was $679.18 \pm 156.40 \mu\text{M}$, which was comparable with the K_m of $707.09 \pm 170.36 \mu\text{M}$ detected by traditional coupled assay. And the K_{cat} was also similar between HPAEC-PAD method (40.43 s^{-1}) and traditional coupled

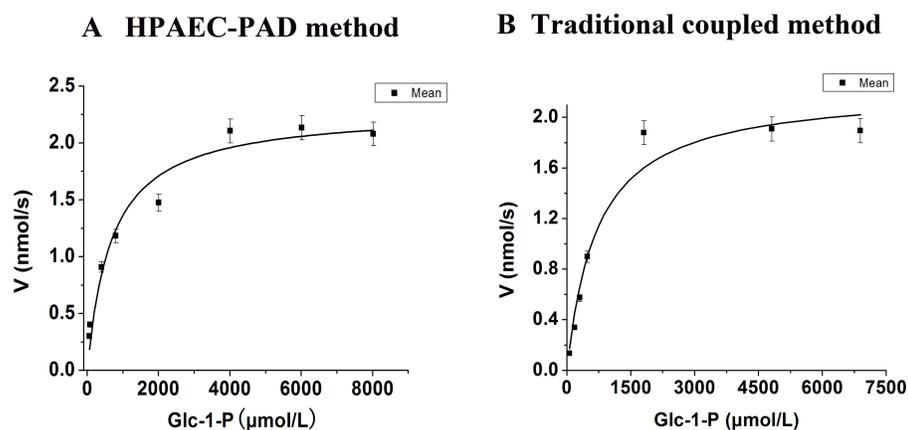

Figure 4 Steady-state kinetics of *AtAGM* was analyzed by using Glc-1-P as substrates by two methods. (A) The HPAEC-PAD method was carried out by using 56.66 pmol *AtAGM* or boiled enzymes, incubated for 10 min at 30 °C in a substrate buffer (300 μ l) consisting of 20 mM PBS, pH 7.0, 10 mM MgSO₄, and 20 μ M glucose-1,6-bisphosphate (Glc-1,6-2P), with varying concentrations of Glc-1-P (60–8,000 μ M). (B) The traditional coupled assay was carried out in a 200 μ l reaction volume containing 20 mM PBS, pH 7.0, 10 mM MgSO₄, 20 μ M glucose-1,6-bisphosphate (Glc-1,6-2P), a range of concentrations of Glc-1-P (60–7,000 μ M), 1 mM NAD⁺ and 2 units of G6PDH, the reaction was started by the addition of 56.66 pmol *AtAGM* and incubated for 10 min at 30 °C. The results are the mean \pm S.D. for three determinations.

Table 1 Kinetic parameters of *AtAGM* was analyzed by using Glc-1-P as substrates by two methods. The HPAEC-PAD method was carried out by using 56.66 pmol *AtAGM* or boiled enzymes, incubated for 10 min at 30 °C in a substrate buffer (300 μ l) consisting of 20 mM PBS, pH 7.0, 10 mM MgSO₄, and 20 μ M glucose-1,6-bisphosphate (Glc-1,6-2P), with varying concentrations of Glc-1-P (60–8,000 μ M). Enzyme	<i>AtAGM</i> (HPAEC-PAD)	<i>AtAGM</i> (Coupled assay)	<i>AfAGM</i> (Fang et al., 2013)
K_m (μ mol L ⁻¹)	679.18 \pm 156.40	707.09 \pm 170.36	400.0 \pm 30.0
V_{max} (nmol s ⁻¹)	2.29 \pm 0.13	2.23 \pm 0.15	0.41 \pm 0.01 (μ M/s)
K_{cat} (s ⁻¹)	40.43	39.32	41.00
K_{cat}/K_m (μ mol L ⁻¹ s ⁻¹)	0.0595	0.0556	0.1025

assay (39.32 s⁻¹). These results were comparable with the K_{cat} (41.00 s⁻¹) obtained from *AfAGM* on the same substrate, which determined by traditional coupled assay (Table 1).

The HPAEC-PAD method was simpler, more convenient than the traditional coupled assay (Greig et al., 2007; Hofmann, Boles & Zimmermann, 1994). The results obtained by the HPAEC-PAD method and traditional coupled assay were very similar, further confirmed the effectiveness of this novel method. Another significant advantage of HPAEC-PAD method was the substrate consuming and the product increasing could be detected at the same time, which enabled the detection of reverse reaction.

GlmM assay

Based on the excellent separation and detection abilities of this novel method on all phosphohexoses, we wonder if this method also could be used to determine the activities of GlmM and PGM besides AGM. GlmM is the second enzyme in hexosamine pathway

Table 2 The activity of *MtGlmM* with GlcN-6-P or GlcN-1-P as substrate was assayed by two methods. The traditional coupled method was assayed in a coupled enzyme system with *MtGlmU*. The 50 μ l reaction mixture contained 50 mM Tris-HCl, pH 8.0, 2.5 mM MgCl₂, 1 mM GlcN-6-P, 0.6 mM acetyl-CoA, 0.2 mM Glc-1,6-2P, purified *MtGlmU* (3.5 μ g) and purified *MtGlmM* (0.18 μ g). The reaction was incubated at 37 °C for 20 min. The HPAEC-PAD method was carried out by using the purified *MtGlmM* (0.18 μ g), incubated at 37 °C for 20 min in a substrate buffer (50 μ l) consisting of 1 mM GlcN-6-P (or GlcN-1-P) as substrate with 50 mM Tris-HCl, pH 8.0, 2.5 mM MgSO₄, and 0.2 mM Glc-1,6-2P. The results are the mean \pm S.D. for three determinations.

Substrates	<i>MtGlmM</i> activity by traditional two-step assay (nmol/min · mg)	<i>MtGlmM</i> activity by direct HPLC assay (nmol/min · mg)
GlcN-6-P	288.97 \pm 35.28	7493.40 \pm 309.12
GlcN-1-P	Can't be measured	6277.90 \pm 385.25

catalyzes the interconversion of GlcN-6-P and GlcN-1-P in prokaryote (Fig. 1B). The well-studied *MtGlmM* from *Mycobacterium tuberculosis* was chosen to validate this idea.

MtGlmM activity was calculated as nanomoles of GlcN-6-P or GlcN-1-P consumed at per minute for per milligram protein (Table 2). It is noteworthy that the activity of *MtGlmM* on GlcN-6-P tested by HPAEC-PAD (7493.40 \pm 309.12 nmol/min · mg) was much higher than the traditional coupled assay (288.97 \pm 35.28 nmol/min · mg). One possible reason was that the accuracy of the traditional coupled assay was mainly dependent on the activity of the coupled enzyme GlmU. GlmU is a bifunctional enzyme (Menginlecreulx & Vanheijenoort, 1993; Menginlecreulx & Vanheijenoort, 1994) (Fig. 1B), catalyzed the third and fourth steps in the prokaryotic hexosamine pathway. In this coupled system, the activity of GlmM was measured indirectly by detecting the generation of CoA-SH, which was catalyzed by the acetyl transferase activity of GlmU (third step). But the acetyl transferase activity of GlmU has a very strong product inhibition when GlcN-1-P reached 0.003 mM (Singh, Das & Seshadri, 2012), so the GlmU become the rate-limiting enzyme in the traditional coupled assay, which result in the significantly decrease of *MtGlmM* activity. Furthermore, GlmU was non-commercial, the expression and purification of GlmU was tedious, which makes the process complicated and the results unstable.

In contrast, HPAEC-PAD method could detect the *MtGlmM* activity directly, which made the detection more sensitive, accurate and convenient. Moreover, HPAEC-PAD method could detect the substrate consuming and the product increasing at the same time, making the detection of reverse reaction possible. The activity of *MtGlmM* on GlcN-1-P tested by HPAEC-PAD was 6277.90 \pm 385.25 nmol/min · mg, which comparable with the activity on GlcN-6-P.

CONCLUSION

A HPAEC-PAD method was developed to analyze the activity of α -D-phosphohexomutases (AGM, PGM and GlmM). This method offers a simple and convenient method to measure the activity of α -D-phosphohexomutases on phosphohexoses. It is more sensitive, accurate and reliable than the traditional coupled assay. This method will bring convenience to further research on α -D-phosphohexomutases.

National High Technology Research and Development Program of China: 2011AA10A205.

CAS Youth Innovation Promotion Association: 2015144.

Competing Interests

The authors declare there are no competing interests.

Author Contributions

- Xiaochen Jia conceived and designed the experiments, performed the experiments, analyzed the data, wrote the paper, prepared figures and/or tables.
- Jian Kang performed the experiments, analyzed the data.
- Heng Yin conceived and designed the experiments, contributed reagents/materials/analysis tools, reviewed drafts of the paper.

Data Availability

The following information was supplied regarding data availability:

The research in this article did not generate any raw data.

Supplemental Information

Supplemental information for this article can be found online at <http://dx.doi.org/10.7717/peerj.1517#supplemental-information>.
