# Thiolated poly(aspartic acid)-functionalized two-dimensional MoS<sub>2</sub>, chitosan and bismuth film as a sensor platform for cadmium ion detection†

 Qiang Cao,<sup>‡,ab</sup> Yushi Xiao,<sup>‡,ab</sup> Rong Huang,<sup>‡,ac</sup> Na Liu,<sup>ab</sup> Hai Chi,<sup>id d</sup> Cheng-Te Lin,<sup>id e</sup> Chi-Hsien Huang,<sup>f</sup> Gang Han<sup>a</sup> and Lidong Wu<sup>id \*a</sup>

In this work, a sensitive electrochemical platform for determination of cadmium ions (Cd<sup>2+</sup>) is obtained using thiolated poly(aspartic acid) (TPA)-functionalized MoS<sub>2</sub> as a sensor platform by differential pulse anodic stripping voltammetry (DPASV). The performance of the TPA–MoS<sub>2</sub>-modified sensor is systemically studied. It demonstrates that the TPA–MoS<sub>2</sub> nanocomposite modified sensor exhibits superior analytical performance for Cd<sup>2+</sup> over a linear range from 0.5 μg L<sup>-1</sup> to 50 μg L<sup>-1</sup>, with a detection limit of 0.17 μg L<sup>-1</sup>. Chitosan is able to form a continuous coating film on the surface of the GC electrode. The good sensing performance of the TPA–MoS<sub>2</sub>-modified sensor may be attributed to the following factors: the large surface area of MoS<sub>2</sub> (603 m<sup>2</sup> g<sup>-1</sup>), and the abundant thiol groups of TPA. Thus, the TPA–MoS<sub>2</sub>-modified sensor proves to be a reliable and environmentally friendly tool for the effective monitoring of Cd<sup>2+</sup> existing in aquacultural environments.

## 1. Introduction

Cadmium (Cd) is one of the priority pollutants due to its high toxicity.<sup>1–3</sup> Cd<sup>2+</sup> not only causes renal tubular dysfunction and bone degeneration (itai-itai disease),<sup>4–6</sup> but is also classified as a carcinogenic chemical by the International Agency for Research on Cancer (IARC).<sup>7–9</sup> Traditionally, inductively coupled plasma mass spectrometry (ICP-MS),<sup>10,11</sup> atomic absorption spectrometry (AAS)<sup>12–14</sup> and ion chromatography<sup>15,16</sup> are used for detecting Cd<sup>2+</sup>. Although these instruments have good precision and high resolution, they are too expensive and labor-intensive.<sup>17,18</sup> Therefore, it is urgent to develop a sensitive method to protect our food, medicine and drinking water from Cd<sup>2+</sup> pollution.

The electrochemical sensor is one of the most promising tools for detecting Cd<sup>2+</sup> due to its low cost, rapid speed, portability and reliability.<sup>19–21</sup> Mercury modified electrode has been intensively used for detecting trace Cd<sup>2+</sup> by differential pulse anodic stripping voltammetry (DPASV).<sup>22,23</sup> However, the toxicity of mercury severely limits its applications in constructing sensors.<sup>24,25</sup> Therefore, bismuth, the less toxicity heavy metal,<sup>26,27</sup> is used for constructing sensors in this work. Except electrode materials, the sensing material also plays an important role in constructing sensors.<sup>28</sup>

As is well known, 2D materials have been established for the sensitive detection methods of environmental pollutants.<sup>29–32</sup> Molybdenum disulfide (MoS<sub>2</sub>) is one of transition-metal dichalcogenides (TMDs), which has a typical layered structure formed by a stack of planes.<sup>33–35</sup> Each layer of MoS<sub>2</sub> consists of three atom layers (S–Mo–S), a layer of molybdenum atoms sandwiched between two layers of sulfur atoms.<sup>36–38</sup> These triple layers are weakly held together by van der Waals forces.<sup>39–41</sup> MoS<sub>2</sub> has unique properties including good flexibility, a tunable bandgap energy controlled by the number of layers and planar electric transportation property.<sup>42–45</sup> Due to its fascinating characteristics, MoS<sub>2</sub> has received much attention for construction of promising electronics devices, for example, field-effect transistors, lithium-ion batteries, *etc.*<sup>46–49</sup> However, exploring more binding sites on MoS<sub>2</sub> for Cd<sup>2+</sup> is still challenging, and this is the key to achieve excellent low detection limit and sensitivity. The poor surface modification of MoS<sub>2</sub> limits its application as electrode material for constructing electrochemical sensors.<sup>50</sup>

‡ Authors equally contribution to this work.

To address this critical challenge, it is predicted that controllable surface modification of MoS<sub>2</sub> could significantly improve the sensitivity of MoS<sub>2</sub> based sensor.<sup>51,52</sup> Thus, in this work, thiolated polymers are chemically adsorbed on electron-rich MoS<sub>2</sub> through covalent bonding. The sulfur on the MoS<sub>2</sub> surface plays as a soft Lewis base showing a high affinity for heavy metal ions (*e.g.*, Bi<sup>3+</sup>, Cd<sup>2+</sup>). MoS<sub>2</sub> demonstrates both a high adsorption capacity due to abundant sulfur adsorption sites and fast kinetics due to easy access to these sites. Therefore, thiolated polymer modified MoS<sub>2</sub> plays as one of the most effective platforms for detecting Cd<sup>2+</sup>. It shows that this sensor possesses superior stability, sensitivity and LOD. The proposed sensor can be used as an environmental-friendly “pre-alarm” tool for rapid determining Cd<sup>2+</sup> in aquaculture water, Chinese drug, food and beverage.

## 2. Experimental section

### 2.1. Materials and solutions

Cadmium chloride, bismuth chloride, and other chemicals are from Tianjin Kermel (Tianjin, China). Thiolated poly(aspartic acid) is obtained from Covestro company (Shanghai, China). 100 mmol L<sup>-1</sup> pH 6.5 acetate buffer is used as the electrolyte in electrochemical experiments.

### 2.2. Apparatus

A JEM-2100 instrument (Japan) is used for obtaining transmission electron microscopy (TEM) images. Scan electron microscopy (SEM) images are obtained by Zeiss Sigma 300 (Germany). A CHI 660B Electrochemical Workstation (Shanghai, China) is used for testing Cd<sup>2+</sup> through DPASV. A functionalized MoS<sub>2</sub> and chitosan film modified glassy carbon (GC) electrode is the working electrode, the Ag/AgCl electrode is the reference electrode, and the platinum wire is the auxiliary electrode. The concentration of Cd<sup>2+</sup> is also confirmed through atomic absorption spectrometry (AAS, Jena, Germany).

### 2.3. Preparation of MoS<sub>2</sub> and modification of GC electrode

MoS<sub>2</sub> nanosheets are prepared by an ultrasonic exfoliation method as literature reported.<sup>53</sup> 1.0 g MoS<sub>2</sub> powder is added into 10 mL *N*-methyl-pyrrolidone solution under ultrasonic wave for 2 h at 0 °C. After centrifugation at 7000 rpm for 30 min, the

prepared MoS<sub>2</sub> nanosheets is dispersed in the supernatant. The 1 mL of 1 mg mL<sup>-1</sup> prepared MoS<sub>2</sub> is mixed with 1 mL 2 mg mL<sup>-1</sup> thiolated poly(aspartic acid) (TPA), and vibrated by vortex for 12 h at room temperature.

The GC electrode is polished by alumina powder (0.05 μm) and washed by ethanol for three times, respectively. Then, 5 μL 0.6 mg mL<sup>-1</sup> functionalized MoS<sub>2</sub> solution, 5 μL chitosan (8 wt%) and 10 μL Milli-Q water are mixed. Finally, 5 μL mixture is immobilized onto the GC electrode to obtain a TPA-MoS<sub>2</sub>/GC electrode.

### 2.4. Cd<sup>2+</sup> detection by TPA-MoS<sub>2</sub>/GC electrode

Bismuth film is plated on the TPA-MoS<sub>2</sub>/GC electrode through the electrodeposition of 10 mg L<sup>-1</sup> Bi<sup>3+</sup> for 210 s with stirring. After coating bismuth film, Cd<sup>2+</sup> is monitored by the TPA-MoS<sub>2</sub>/GC electrode in 8 mL 100 mmol L<sup>-1</sup> acetate buffer (pH 6.5).

## 3. Results and discussion

### 3.1. TEM characterization of MoS<sub>2</sub>

MoS<sub>2</sub> was obtained through ultrasonic exfoliation method. Fig. 1 showed representative TEM images of the MoS<sub>2</sub> nanosheets (A), the functionalized MoS<sub>2</sub> (B) and the functionalized MoS<sub>2</sub> deposited with bismuth and cadmium (C). It suggested that the prepared MoS<sub>2</sub> nanosheets were very thin and clear. After TPA non-covalent modified on the MoS<sub>2</sub> nanosheets, the original morphology of the MoS<sub>2</sub> nanosheets was retained in the composites. Fig. 1C is a TEM image of the TPA-MoS<sub>2</sub>-Bi-Cd nanocomposites and clearly showed the modification of the MoS<sub>2</sub> by Bi and Cd nanocluster. As shown in Fig. S1,† TPA-MoS<sub>2</sub> surface becomes rough and there are lots of nanoparticles on the surface of TPA-MoS<sub>2</sub> after detection. It is consistent with TEM images. FTIR was also used to confirm the formation of TPA on the MoS<sub>2</sub> nanosheets. As shown in Fig. 2, the peak of 2550 cm<sup>-1</sup> was the SH group of TPA. After TPA modified on the MoS<sub>2</sub> nanosheets, the absorption bands at 1390 (symmetric stretching of -COOH), 1600 (asymmetric stretching of -COOH), and 3000–3500 cm<sup>-1</sup> (NH<sub>3</sub><sup>+</sup> stretch) became weak. The change in their dipole moment was due to TPA modification on the MoS<sub>2</sub> nanosheets. These results showed the successful modification of TPA on the MoS<sub>2</sub> nanosheets. X-ray photoelectron spectroscopy (XPS) was used to determine the chemical composition and states of the TPA-MoS<sub>2</sub>

Fig. 1 TEM image of MoS<sub>2</sub> nanosheets (A), the TPA functionalized MoS<sub>2</sub> (B), and the TPA-MoS<sub>2</sub> with bismuth and cadmium (C).

Fig. 2 FTIR image of TPA and TPA-MoS<sub>2</sub>.

with cadmium. As shown in Fig. S2A,† two peaks at 229 and 232 eV energy values ascribed to Mo core peaks, and the peak at 226 eV ascribed to S core peak. Fig. S2B† showed two peaks at 163 and 161.7 eV. These binding energy values are consistent with the expected charge states of Cd<sup>2+</sup>, Mo<sup>4+</sup> and S<sup>2-</sup>. Furthermore, the specific surface area of the MoS<sub>2</sub> nanosheets was estimated by the Brunauer-Emmett-Teller (BET) method. Its specific surface area achieved to be 603 m<sup>2</sup> g<sup>-1</sup>. The high effective surface area and high-quality of MoS<sub>2</sub> could provide good performances for GC electrode.

### 3.2. Electrochemical characterization of the TPA-MoS<sub>2</sub>-modified GC electrode

Cyclic voltammetry (CV) was an electrochemical measurement method which could be used for monitoring the preparation procedure of GC electrode. As shown in Fig. 3, the immobilization process of the TPA-MoS<sub>2</sub>/GC electrode was performed. Fig. 3 displayed the CVs of the bare GC, MoS<sub>2</sub>/GC and TPA-MoS<sub>2</sub>/GC electrodes in 2 mmol L<sup>-1</sup> K<sub>3</sub>[Fe(CN)<sub>6</sub>]/K<sub>4</sub>[Fe(CN)<sub>6</sub>] solution. The CV of the bare GC electrode was highest among these electrodes. It demonstrated that the electron transfer rate between [Fe(CN)<sub>6</sub>]<sup>3-/4-</sup> and the bare electrode was very fast. The CV of the TPA-MoS<sub>2</sub>/GC electrode was the lowest, which demonstrated that a chitosan film and TPA-MoS<sub>2</sub> had covered on the surface of the bare GC electrode. Without modification of

Fig. 3 Cyclic voltammograms of bare GC, MoS<sub>2</sub>/GC and TPA-MoS<sub>2</sub>/GC electrodes in 2 mmol L<sup>-1</sup> [Fe(CN)<sub>6</sub>]<sup>3-/4-</sup> at a scan rate of 100 mV s<sup>-1</sup>.

Fig. 4 (A) DPASVs obtained for different concentrations of Cd<sup>2+</sup> using a bismuth-coated TPA-MoS<sub>2</sub>/GC electrode; from bottom to top, 0.5, 10, 25, 50, 75, 100 µg L<sup>-1</sup> with 10 mg L<sup>-1</sup> Bi<sup>3+</sup> electrodeposited for 210 s under stirring in 100 mmol L<sup>-1</sup> acetate buffer (pH 5.0). (B) Calibration curves of MoS<sub>2</sub>/GC (red color) and TPA-MoS<sub>2</sub>/GC (black color) electrodes for Cd<sup>2+</sup>.

TPA, the MoS<sub>2</sub> nanosheets possessed good conductivity, and the CV of the chitosan-MoS<sub>2</sub>/GC electrode was higher than the TPA-MoS<sub>2</sub>/GC electrode. The results might be due to the introduction of TPA, which played a key role in improving the binding sites of Cd<sup>2+</sup>. It also showed that the TPA-MoS<sub>2</sub> and chitosan film had covered on the GC electrode.

### 3.3. The TPA-MoS<sub>2</sub>-modified GC electrode for Cd<sup>2+</sup> analysis

In this study, DPASV was used for detecting Cd<sup>2+</sup>. Fig. 4A showed that the DPASVs of the MoS<sub>2</sub>/GC and the TPA-MoS<sub>2</sub>/GC electrodes increased with the concentrations of Cd<sup>2+</sup> from 0.5 to 100 µg L<sup>-1</sup> in 100 mmol L<sup>-1</sup> acetate buffer (pH 6.5) with 10 mg L<sup>-1</sup> Bi<sup>3+</sup> electrodepositing for 210 s. After the concentrations of Cd<sup>2+</sup> achieved 150, 200 and 250 µg L<sup>-1</sup>, the DPASVs of these electrodes increased unobvious. The DPASVs response signals increased linearly from 0.5 to 100 µg L<sup>-1</sup> then become flat. As shown in Fig. 4B, the current peaks increased linearly with Cd<sup>2+</sup> concentration, and the correlation coefficients was approximate 0.99. The sensitivity of the MoS<sub>2</sub>/GC and the TPA-MoS<sub>2</sub>/GC electrodes were 101.8 and 178.2 mA cm<sup>-2</sup> m<sup>-1</sup>, respectively. Furthermore, the detection limit (DL) was an

Fig. 5 The stability of 10 repetitive measurements of  $50 \mu\text{g L}^{-1} \text{Cd}^{2+}$  in  $0.1 \text{ mol L}^{-1}$  acetate buffer (pH 5.0) containing  $3 \text{ mg L}^{-1} \text{Bi}^{3+}$ .

Table 1 Comparison of  $\text{Cd}^{2+}$  concentration in different aquaculture water samples by the sensor and AAS method

Sample	Concentration ( $\mu\text{g L}^{-1}$ ) (sensor method)	Concentration ( $\mu\text{g L}^{-1}$ ) (AAS method)	Difference <sup>a</sup> (%)
A	1.9	1.7	11.76
B	—	—	—
C	—	—	—
D	2.1	2.4	-12.5
E	—	—	—
F	—	—	—

<sup>a</sup> Difference = (sensor(value) – AAS(value))/AAS(value) × 100%.

important parameter as sensors. The DL of the TPA-MoS<sub>2</sub>/GC and the MoS<sub>2</sub>/GC electrodes achieved  $0.2 \mu\text{g L}^{-1}$  and  $0.5 \mu\text{g L}^{-1}$  at a signal-to-noise ratio of 3, respectively. It demonstrated that the DL ( $0.2 \mu\text{g L}^{-1}$ ) of the TPA-MoS<sub>2</sub>/GC electrode was much lower than the standard for detecting tap water quality in China (GB 5749-2006, Cd  $0.005 \text{ mg L}^{-1}$ ). The DL of the TPA-MoS<sub>2</sub>/GC electrode was superior to that of the chitosan-multiwalled carbon nanotubes/GC electrode ( $0.4 \mu\text{g L}^{-1}$ , electrodeposition Bi<sup>3+</sup> for 300 s). Reproducibility was another important parameter of sensors. As shown in Fig. 5, 10 repeated measurements for  $50 \mu\text{g L}^{-1} \text{Cd}^{2+}$  had excellent reproducibility with relative standard deviation (RSD) of 0.41%. Therefore, this prepared sensor could be potentially applied to rapid detection of Cd<sup>2+</sup> in the aquaculture water.

Table 2 Analysis of Cd<sup>2+</sup> by different reported methods

Electrode	Detection limit ( $\mu\text{g L}^{-1}$ )	Deposition time (s)	Ref.
TPA-MoS <sub>2</sub>	0.17	210	Present work
Bi-coated GC	50	120	54
Bi-GP-CNT/GC	0.6	150	55
Bi-Nafion/GC	1.39	120	56

### 3.4. The TPA-MoS<sub>2</sub>/GC electrode testing aquaculture water samples

This sensor was used for detecting Cd<sup>2+</sup> in the aquaculture water samples. The test samples were directly added into the bottle without enrichment, and then detected by the TPA-MoS<sub>2</sub>/GC electrode according to previous procedure. The Cd<sup>2+</sup> standard solution ( $50 \mu\text{g L}^{-1}$ ) was added into the bottle to calculate and correct the results of the test samples. A  $0.22 \mu\text{m}$  filter membrane was used for extracting 6 aquaculture water samples. As shown in Table 1, the Cd<sup>2+</sup> concentration in aquaculture water A and aquaculture water D were  $1.9$  and  $2.1 \mu\text{g L}^{-1}$ , respectively. For other samples (sample B, sample C, sample E and sample F), there was no Cd<sup>2+</sup>. The concentration of aquaculture water samples was validated by AAS. It indicated that the sensor was a reliable and sensitive tool for the rapid detection of Cd<sup>2+</sup> in real samples.

The good sensing performance of the TPA-MoS<sub>2</sub>/GC electrode might be attributed to the following factors: the large surface area of MoS<sub>2</sub> greatly increased the active surface area of the GC electrode for Cd<sup>2+</sup> adsorption, and the abundant thiol group of TPA significantly increased the binding sites for Cd<sup>2+</sup> (Scheme 1); the good electric conductivity of MoS<sub>2</sub> could improve the electron transfer rate between the surface of the GC electrode and Cd<sup>2+</sup> in the bulk solution; and the 2D nanostructure provided a very broad space for the easy transfer of Cd<sup>2+</sup>. Based on these reasons, the TPA-MoS<sub>2</sub>/GC electrode exhibited low DL and good reproducibility (Table 2). Thus, the TPA-MoS<sub>2</sub>/GC electrode showed greater potential for use as a “pre-alarm” tool.

## 4. Conclusion

In summary, the TPA-MoS<sub>2</sub>/GC electrode was prepared for Cd<sup>2+</sup> detection in the aquaculture water samples. It showed that the TPA-MoS<sub>2</sub> nanocomposites offered significant advantages, such as low DL and good reproducibility. The good results were

Scheme 1 Schematic diagram of Cd<sup>2+</sup> absorption on TPA-MoS<sub>2</sub> nanocomposites.

attributed to the large specific surface area, abundant thiol group from TPA and high electrical conductivity of the TPA-MoS<sub>2</sub> nanocomposites. Furthermore, the bismuth electrode provided more environmental-friendly electrode for researcher health. The TPA-MoS<sub>2</sub>/GC electrode possessed greatly potential for its application in the on-site rapid analysis of Cd<sup>2+</sup> in the water or food.
