

Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.

Short communication

Supraclavicular lymphadenopathy following COVID-19 vaccination: an increasing presentation to the two-week wait neck lump clinic?

Abstract

The first COVID-19 vaccination was given in December 2020 and there is an effort to vaccinate the international population on a massive scale. Common side effects from the vaccine include headache and tiredness. Regional lymphadenopathy has been described in relation to other vaccines. We describe two cases of supraclavicular reactive lymphadenopathy presenting in patients who had the COVID vaccination in the ipsilateral arm. Awareness of this diagnosis is important for patients presenting to the neck lump clinic.

Keywords: COVID-19; lymphadenopathy; neck lump

The first COVID-19 vaccination was given to an NHS patient on 8 December 2020.¹ Since then over fifteen million people have received the vaccine in England and this number will significantly increase as the population is offered it.² Common side effects include a sore arm, tiredness, headaches, and general malaise.

We report two cases of reactive supraclavicular lymphadenopathy following COVID-19 vaccination presenting at the same two-week wait neck lump clinic. A 47-year-old and a 55-year-old female, both otherwise fit and well, had received the COVID vaccination in their left arms three weeks previously. They both then developed a swollen left supraclavicular lymph node about three days later and were referred to the urgent neck lump clinic on the two-week wait cancer pathway to exclude malignancy. One of the patients reported that the lump had since reduced in size. Clinical and ultrasonographic examination confirmed the lumps as reac-

tive lymph nodes (Fig. 1). No other neck lymphadenopathy was identified and both patients were reassured and discharged.

Cervical lymphadenopathy has been reported as a side effect to other vaccinations such the human papilloma and influenza vaccinations.^{3–5} Axillary lymphadenopathy mimicking breast cancer has recently been described as a side effect of the COVID-19 vaccination.⁶ While the lymphatic pathway from the arm mainly drains to the axillary nodes there are also connections to the supraclavicular nodes in the low neck. To our knowledge this is the first report of COVID-19 vaccination related lymphadenopathy mimicking a Virchow-node type presentation.

With the increasing roll-out of the COVID vaccination to the wider population we suspect that neck lump clinics will see more patients being referred with COVID-19 vaccination-related reactive lymphadenopathy. It is worth considering this ‘new’ diagnosis in the differential list and asking patients whether they have received the vaccination recently.
