## ABSTRACT

The catalytic generation of H<sub>2</sub> in living cells provides a method for antioxidant therapy. In this study, an [FeFe]-hydrogenase mimic [Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80)] was synthesized by self-assembling polymeric pluronic F-127, catalytic [Fe<sub>2</sub>S<sub>2</sub>] sites, and photosensitizer Ru(bpy)<sub>3</sub><sup>2+</sup>. Under blue light irradiation, hydrated protons were photochemically reduced to H<sub>2</sub>, which increased the local pH in living cells (HeLa cells). The generated H<sub>2</sub> was subsequently used as an antioxidant to decrease reactive oxygen species (ROS) levels in living cells (HEK 293T, HepG2, MCF-7, and HeLa cells). Our findings revealed that the proliferation of HEK 293T cells increased by a factor of about six times, relative to that of other cells (HepG2, MCF-7, and HeLa cells). Intracellular ROS and pH levels were then monitored using fluorescent cell imaging. Our study showed that cell imaging can be used to evaluate the ability of Ru + Fe<sub>2</sub>S<sub>2</sub>@F127 to eliminate oxidative stress and prevent ROS-related diseases.

## 1. Introduction

Reactive oxygen species (ROS), including O<sub>2</sub><sup>-</sup>, hydroxyl radicals (·OH), and H<sub>2</sub>O<sub>2</sub>, play significant roles in regulating physiological activities. In healthy living cells, ROS are maintained at low levels. Abnormal overproduction of ROS is implicated in oxidative stress, which is associated with various diseases such as cancer, cardiovascular diseases, and neurological disorders [1–3]. Recent research has demonstrated that hydrogen (H<sub>2</sub>) functions as an effective antioxidant and can be used as a therapeutic medical gas in the clinic [4–6]. Furthermore, H<sub>2</sub> not only reacts with ·OH and peroxynitrite (ONOO<sup>-</sup>), but also reduces cell apoptosis [7–9]. As an alternative to H<sub>2</sub>, H<sub>2</sub>-rich saline is suitable for clinical application in the treatment of ischemia-reperfusion injury [10], Alzheimer's and Parkinson's diseases [11], acute pancreatitis [12], and other oxidative stress-related diseases [13].

[FeFe]-hydrogenase ([FeFe]-H<sub>2</sub>ase), a metalloenzyme extracted from green algae, is an effective biocatalyst for reducing hydrated protons to molecular H<sub>2</sub> [14]. Mimics of the [FeFe]-H<sub>2</sub>ase active center, a [Fe<sub>2</sub>S<sub>2</sub>] cluster, have shown promise as catalysts for hydrated proton

reduction. In particular, H<sub>2</sub> generation can be dramatically enhanced via artificial photocatalytic systems by combining [FeFe]-H<sub>2</sub>ase mimics with photosensitizers (PSs) [15–17]. Since the first photocatalytic system was synthesized by Sun and co-workers in 2003 [18], similar artificial systems have been designed to produce H<sub>2</sub> under visible light irradiation. [Fe<sub>2</sub>S<sub>2</sub>] cluster-based photocatalytic systems are generally prepared by the following two methods: 1) linking PS to the active center of [FeFe]-H<sub>2</sub>ase, and 2) incorporating [FeFe]-H<sub>2</sub>ase mimics into self-assembling systems containing PS [19–21]. Briefly, photoinduced electron transfer from PS to the [Fe<sub>2</sub>S<sub>2</sub>] cluster is important for photocatalytic H<sub>2</sub> production.

Herein, we propose an [Fe<sub>2</sub>S<sub>2</sub>] cluster-based nanoarchitecture as an [FeFe]-H<sub>2</sub>ase mimic for antioxidant H<sub>2</sub> photogeneration therapy. The nanoarchitecture was self-assembled from biologically inert pluronic F-127, [Fe<sub>2</sub>S<sub>2</sub>] cluster, and PS [Ru(bpy)<sub>3</sub><sup>2+</sup>] (Fig. 1). Pluronic F-127 is a triblock copolymer that contains a central poly(propylene oxide) (PPO) block flanked by two poly(ethylene oxide) (PEO) units. Self-assembled spherical pluronic F-127 micelles have good biocompatibility, making them excellent candidates for drug carriers [22,23]. The [Fe<sub>2</sub>S<sub>2</sub>] clusters and Ru(bpy)<sub>3</sub><sup>2+</sup> were loaded into spherical pluronic F-127 micelles. This self-assembled system (Ru + Fe<sub>2</sub>S<sub>2</sub>@F127) was capable of photochemically generating H<sub>2</sub> under visible-light irradiation.

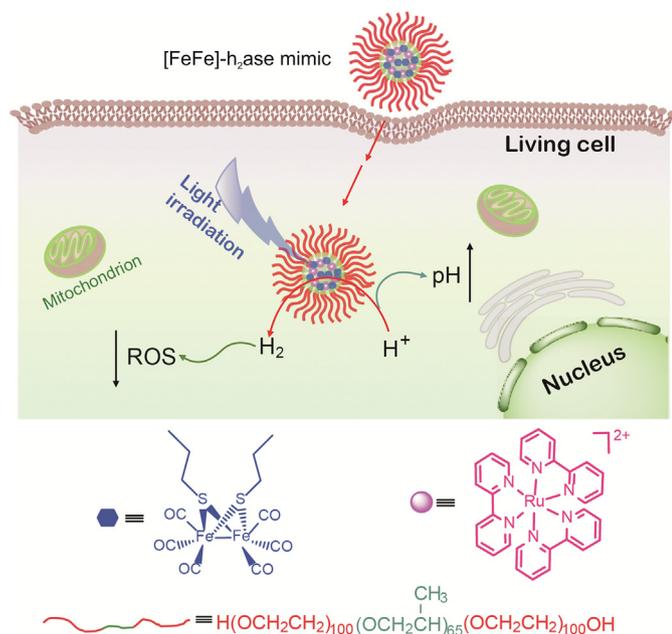

Overconsumption of oxygen in tumor tissues or inflammatory sites can lead to an acidic environment. Endosomes or lysosomes in

**Fig. 1.** [FeFe]-H<sub>2</sub>ase nanoarchitecture (Ru + Fe<sub>2</sub>S<sub>2</sub>@F127) for moderating reactive oxygen species (ROS) and pH levels in living cancer cells.

cancer cells involved in the uptake of nanomaterials are slightly acidic [24,25]. In addition, the ROS levels in cancer cells are higher than those in healthy cells. Low pH and high oxidative stress may also damage healthy cells, resulting in their transformation into cancer cells and tumor aggravation. Inspired by the effective antioxidant ability of H<sub>2</sub>, HeLa cells were used as a model to investigate the ROS and pH moderating ability of Ru + Fe<sub>2</sub>S<sub>2</sub>@F127 nanoarchitectures, which can be endocytosed into cancer cells. Under visible light, Ru + Fe<sub>2</sub>S<sub>2</sub>@F127 can photochemically reduce hydrated protons to H<sub>2</sub> and increase local pH. The generated H<sub>2</sub> was then used as an antioxidant to decrease ROS levels. The probes 2',7'-dichlorodihydrofluorescein diacetate (DCHF-DA) and 2,7-bis(2-carboxyethyl)-5(6)-carboxyfluorescein tetrakis(acetoxymethyl) ester (BCECF-AM) were used to monitor intracellular ROS and pH levels, respectively. The imaging results show that this catalytic system provides a potential approach to increasing endogenous antioxidative protection and repairing the acid-base environment in living cells, especially in healthy cells around cancer tissues.

## 2. Materials and methods

### 2.1. Materials

Pluronic F-127, Ru(bpy)<sub>3</sub>Cl<sub>2</sub>, Fe<sub>3</sub>(CO)<sub>12</sub>, 1-propanethiol, and BCECF-AM were purchased from Sigma-Aldrich (St. Louis, MO, USA). MitoTracker Deep Red FM (MTDR) and 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl-tetrazoliumbromide (MTT) were purchased from YEASEN (Shanghai, China). DCHF-DA was purchased from Sigma-Aldrich (St. Louis, MO, USA). Other reagents were purchased from Nanjing Chemical Reagent Co., Ltd. (Nanjing, China), and were of analytical grade. All aqueous solutions were prepared using deionized water (18 MΩ·cm; Pall Purelab Classic, New York City, NY, USA).

### 2.2. Instruments

The morphology of the Ru + Fe<sub>2</sub>S<sub>2</sub>@F127 nanoarchitecture was characterized using transmission electron microscopy (TEM; JEM-

200CX, Tokyo, Japan). Fluorescence spectra were recorded using an RF-5301PC spectrophotometer (Shimadzu, Kyoto, Japan). Ultraviolet-visible (UV-vis) spectra were recorded on a UV-1800 spectrophotometer (Shimadzu, Kyoto, Japan). Fourier transform infrared (FT-IR) spectra were collected using a Bruker TENSOR 27 spectrometer (Bruker, Karlsruhe, Germany). Cell images were obtained using a TCS SP5 laser scanning confocal microscope (Leica, Heidelberg, Germany).

### 2.3. Methods

#### 2.3.1. Synthesis of [Fe<sub>2</sub>S<sub>2</sub>] cluster (1-[Fe<sub>2</sub>S<sub>2</sub>])

Solid Fe<sub>3</sub>(CO)<sub>12</sub> (100 mg, 0.2 mmol) and 1-propanethiol (36 μL, 0.4 mmol) were added to tetrahydrofuran (THF) (10 mL) under a N<sub>2</sub> atmosphere. The mixture was refluxed under N<sub>2</sub> for 2 h, and the color of the solution turned from dark green to red. The solvent was removed by vacuum evaporation, and the crude product was loaded onto a silica column (20 cm × 1.5 cm) and eluted with hexane to remove excess starting material. A red-orange crystalline product was obtained with a yield of approximately 70%. <sup>1</sup>H nuclear magnetic resonance (400 MHz, CDCl<sub>3</sub>): δ2.7 (4H, m, SCH<sub>2</sub>), δ1.7 (4H, m, -CH<sub>2</sub>-), δ1.1 (6H, m, -CH<sub>3</sub>). FT-IR (KBr): ν<sub>(-CH<sub>2</sub>-)</sub> = 2928 cm<sup>-1</sup>, ν<sub>(-CH<sub>3</sub>)</sub> = 2971 cm<sup>-1</sup>, ν<sub>(-C=O)</sub> = 1984 cm<sup>-1</sup>.

#### 2.3.2. Synthesis of Ru + Fe<sub>2</sub>S<sub>2</sub>@F127

Pluronic F-127 (20, 40, and 80 mg), Ru(bpy)<sub>3</sub>Cl<sub>2</sub> (1 mg), and 1-[Fe<sub>2</sub>S<sub>2</sub>] (1 mg) were dissolved in 0.6 mL of THF. After the THF was evaporated under vacuum, 1 mL of deionized water was added to the mixture, which was then stirred overnight at room temperature. The prepared Ru + Fe<sub>2</sub>S<sub>2</sub>@F127 micelles were collected by centrifugation at 9,000 r/min for 20 min and then re-dispersed in 1 mL of deionized water for the following experiment. The size of the Ru + Fe<sub>2</sub>S<sub>2</sub>@F127 micelles was characterized by TEM.

#### 2.3.3. Photocatalytic hydrogen production

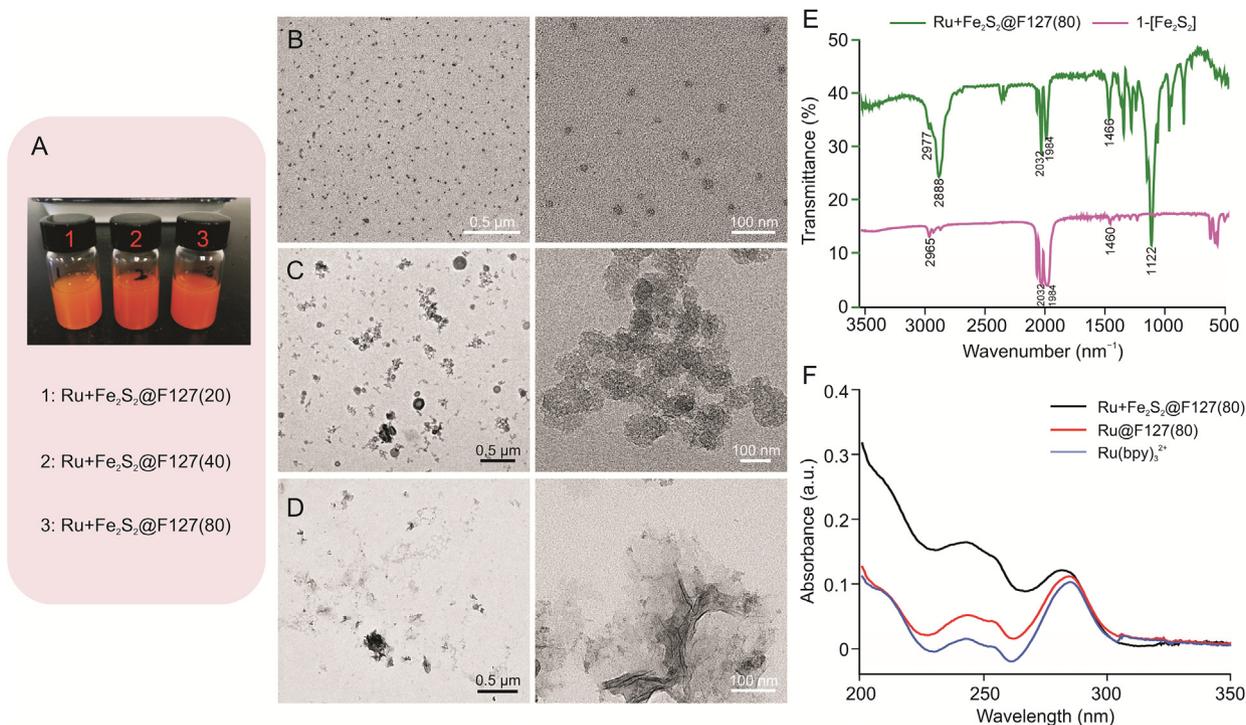

The Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) suspension (100, 300, or 500 μL) was added to 5 mL of citrate buffer (50 mM, pH 4.5) containing 50 mM ascorbate. Before starting the photocatalytic experiment, the reaction mixture was purged with N<sub>2</sub> for 40 min. The sample was irradiated with light-emitting diodes (blue light, 50 W, λ = 400–480 nm). The generated H<sub>2</sub> was determined by gas chromatograph (GC) (Shimadzu GC2014, Kyoto, Japan) using a molecular sieve column (5 Å), loop size (3 mL), and a thermal conductivity detector.

#### 2.3.4. Cell culture

HeLa, MCF-7, HepG2, and HEK 293T cells were cultured in Dulbecco's modified Eagle's medium supplemented with 10% fetal bovine serum (both from GIBCO, Grand Island, NY, USA), 5% penicillin streptomycin glutamine, and 5% sodium pyruvate at 37 °C in a humidified atmosphere containing 5% CO<sub>2</sub>. Before the cell imaging experiments, HeLa cells were seeded in cell culture dishes and incubated for 24 h.

#### 2.3.5. Intracellular ROS imaging

The Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) suspension (20 μL) was added to cells in culture dishes, and the specimens were incubated for 30 min. After ·OH generation (Fenton reaction by 75 μM FeCl<sub>2</sub> + 150 μM H<sub>2</sub>O<sub>2</sub> + 75 μM ethylenediamine tetraacetic acid (EDTA)) for 10 min, the cells were irradiated with light-emitting diodes (blue light, 50 W, λ = 400–480 nm) for 5 min or 10 min. The medium was removed, and the cells were washed with phosphate-buffered saline (PBS). Then MTDR (200 nM) was added, and the samples were incubated for 20 min, washed with PBS five

**Fig. 2.** Characterization of the Ru + Fe<sub>2</sub>S<sub>2</sub>@F127 nanoarchitectures. (A) Ru + Fe<sub>2</sub>S<sub>2</sub>@F127 nanoarchitecture dispersed in water; nanoparticles with increasing pluronic F-127 content: Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(20), Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(40), and Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80). Transmission electron microscopy (TEM) images of (B) Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80), (C) Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(40), and (D) Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(20). (E) Fourier transform infrared (FT-IR) spectra of Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) and 1-[Fe<sub>2</sub>S<sub>2</sub>]. times, and incubated with DCHF-DA (200 nM) for 30 min. After washing with PBS, confocal fluorescence imaging was performed.

### 2.3.6. Ethidium bromide/acridine orange (EB/AO) staining

The Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) suspension (20 μL) was added to HeLa cell culture dishes and incubated for 30 min. Then, Fenton reagent (75 μM FeCl<sub>2</sub> + 150 μM H<sub>2</sub>O<sub>2</sub> + 75 μM EDTA) was added and incubated for 10 min. HeLa cells were irradiated by light-emitting diodes (blue light, 50 W, λ = 400–480 nm) for 0, 2, 5, or 10 min. After 10 h, the cells were stained with EB/AO (100 μg/mL AO and 100 μg/mL EB) for 30 min for confocal fluorescence imaging.

### 2.3.7. Intracellular pH imaging

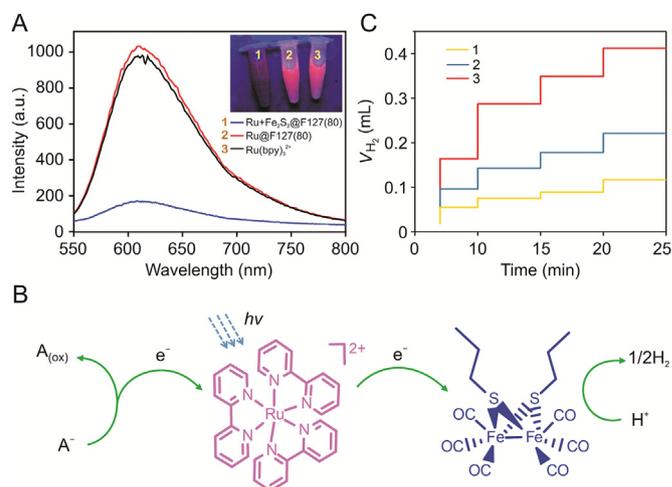

The Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) suspension (20 μL) was added to cells in culture dishes, and the specimens were incubated for 30 min. The cells were irradiated by light-emitting diodes (blue light, 50 W, λ = 400–480 nm) for 10 min. BCECF-AM (250 nM) was then added, and the cells were incubated for 30 min. The cells were then washed with PBS prior to confocal fluorescence imaging.

### 2.3.8. Cell proliferation measurements

HeLa cells were seeded in six dishes and incubated under the same conditions for 24 h. Among the samples, one dish was treated with Fenton reagent as the control sample, and the other five dishes were treated with Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) and ROS, generated by the Fenton reaction. HeLa cells in the five dishes that contained Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) were irradiated with light-emitting diodes for 0, 2, 5, 10, and 14 min. The cells were then incubated for another 12 h and stained with AO solution (100 μg/mL) for 30 min. After washing with PBS, the living cells were counted using a fluorescent microscope.

## 3. Results and discussion

The active sites of mimics of [FeFe]-H<sub>2</sub>ase for the chemical reduction of hydrated protons usually feature three central components: iron, thiolate groups, and carbon monoxide [26,27]. Combined with either electrochemical or photochemical reactions, improved catalytic performance of the [FeFe]-H<sub>2</sub>ase mimics has been achieved [15,16,28]. In this study, an [Fe<sub>2</sub>S<sub>2</sub>] cluster (1-[Fe<sub>2</sub>S<sub>2</sub>]) was

**Fig. 3.** Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) nanoarchitectures for hydrogen production. (A) Fluorescence spectra of Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80), Ru@F127(80), and Ru(bpy)<sub>3</sub><sup>2+</sup> (λ<sub>ex</sub> = 470 nm). The inset shows the visible fluorescence changes under irradiation with 365 nm light. (B) Reaction scheme for the photocatalytic reduction of hydrated protons to hydrogen. (C) Photocatalytic hydrogen production in the presence of different volumes of Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) suspension. 1: 100 μL; 2: 300 μL; 3: 500 μL.

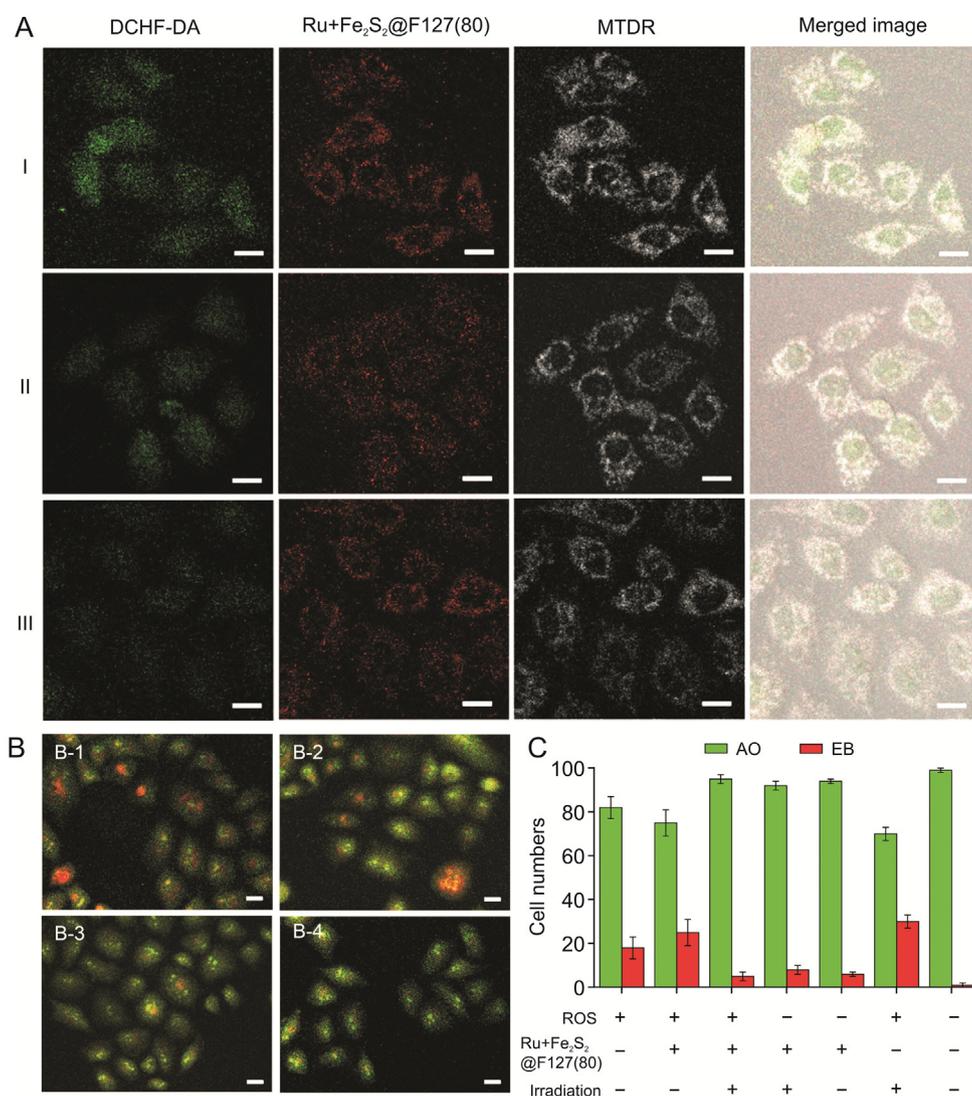

synthesized to mimic [FeFe]-H<sub>2</sub>ase. As shown in Scheme S1, hydrophobic 1-[Fe<sub>2</sub>S<sub>2</sub>] was synthesized from Fe<sub>3</sub>(CO)<sub>12</sub> and 1-propanethiol. Ru(bpy)<sub>3</sub>Cl<sub>2</sub> was employed as a photosensitizer to supply the photogenerated electrons. To improve the photocatalytic efficiency for hydrogen evolution, a spatially confined nanoarchitecture of Ru + Fe<sub>2</sub>S<sub>2</sub>@F127 was synthesized by embedding 1-[Fe<sub>2</sub>S<sub>2</sub>] and Ru(bpy)<sub>3</sub>Cl<sub>2</sub> into pluronic micelles containing (PEO)<sub>m</sub>(PPO)<sub>n</sub>(PEO)<sub>m</sub> ( $m = 100$ ,  $n = 65$ , molecular weight = 12,600) [29–31]. A homogeneous mixture of 1-[Fe<sub>2</sub>S<sub>2</sub>], Ru(bpy)<sub>3</sub>Cl<sub>2</sub>, and pluronic F-127 in THF was first prepared. After adding water to the dried mixture, the triblock pluronic F-127 aggregated into micelles. Additionally, 1-[Fe<sub>2</sub>S<sub>2</sub>] and Ru(bpy)<sub>3</sub>Cl<sub>2</sub> were incorporated into the hydrophobic PPO core.

Different weight ratios of pluronic F-127, Ru(bpy)<sub>3</sub>Cl<sub>2</sub>, and 1-[Fe<sub>2</sub>S<sub>2</sub>] (20:1:1, 40:1:1, and 80:1:1, respectively) were used to synthesize the Ru + Fe<sub>2</sub>S<sub>2</sub>@F127 nanoarchitectures. The three types of Ru + Fe<sub>2</sub>S<sub>2</sub>@F127 nanoarchitectures were denoted as Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(20), Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(40), and Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80), according to the proportion of pluronic F-127. As shown in Fig. 2A, all three types of Ru + Fe<sub>2</sub>S<sub>2</sub>@F127 were stably dispersed in water. However, the morphologies

dramatically differed (Figs. 2B–D). The TEM images show that Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(20) did not have a nanoparticle structure (Fig. 2D). With the increased pluronic F-127 concentration, a particulated Ru + Fe<sub>2</sub>S<sub>2</sub>@F127 nanostructure formed, and its size decreased with the increased pluronic F-127 concentration. Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) showed a uniform particle size (approximately 10 nm), which was further applied in the study.

The composition of Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) was investigated using FT-IR and UV spectroscopy (Figs. 2E, F, and S1). The UV spectrum of Ru(bpy)<sub>3</sub><sup>2+</sup> in Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) was characterized by an absorption band of the bpy groups at 284 nm. The alkyl and alkoxy groups of 1-[Fe<sub>2</sub>S<sub>2</sub>] and pluronic F-127 showed strong absorption around 200 nm. The FT-IR spectrum of Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) showed characteristic absorption bands of  $\nu_{(-C=O)} = 1984 \text{ cm}^{-1}$  from 1-[Fe<sub>2</sub>S<sub>2</sub>]. The absorption signal at  $2977 \text{ cm}^{-1}$  indicated the existence of  $\nu_{(O-H)}$  in Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80), and the signal at approximately  $2888 \text{ cm}^{-1}$  is attributed to  $\nu_{(C-H)}$ .

The fluorescence emission properties of Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) are shown in Fig. 3A. Ru@F127(80) was prepared using the same method as Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80), but without 1-[Fe<sub>2</sub>S<sub>2</sub>], and this sample was

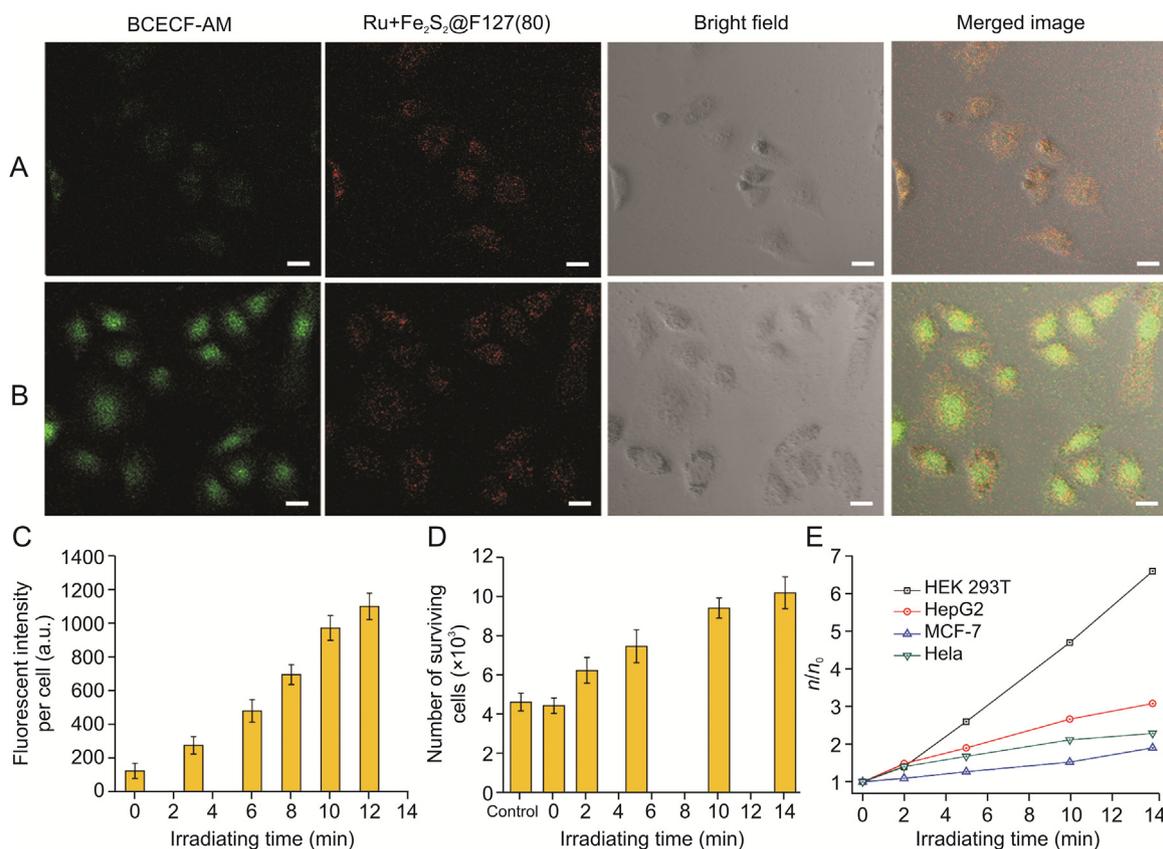

**Fig. 4.** Moderating reactive oxygen species (ROS) levels in Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80)-loaded HeLa cells. (A) Confocal images of intracellular ROS visualization after the cells were irradiated by blue light for 0 (I), 5 (II), and 10 min (III). Scale bar: 30  $\mu\text{m}$ . (B) Confocal images of HeLa cells stained with ethidium bromide/acridine orange (EB/AO) after the cells were irradiated by blue light for 0 (B-1), 2 (B-2), 5 (B-3), and 10 min (B-4). Scale bar: 30  $\mu\text{m}$ . (C) Numbers of EB- and AO-positive HeLa cells stained by EB/AO (the ROS was generated by Fenton reagent). The counted total cell number was 100 ( $n = 3$ ). DCHF-DA: 2',7'-dichlorodihydrofluorescein diacetate; MTRD: MitoTracker Deep Red FM.

used as a control (Fig. S2). The fluorescence intensity of Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) was significantly lower than that of Ru@F127(80), indicating that electron and/or energy transfer occurred from the photosensitizer (Ru(bpy)<sub>3</sub><sup>2+</sup>) to the catalyst (1-[Fe<sub>2</sub>S<sub>2</sub>]), resulting in fluorescence quenching. The photocatalytic reduction of hydrated protons by Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) commenced with the reductive quenching of photoexcited Ru(bpy)<sub>3</sub><sup>2+</sup>. The electron transfer path during hydrogen generation is shown in Fig. 3B. By using ascorbate as an electron donor, the self-assembled system [Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80)] could produce H<sub>2</sub> under visible-light irradiation. As shown in Fig. S3, bubbles were clearly observed after light irradiation of the catalytic system. The generated H<sub>2</sub> was analyzed using GC. Fig. 3C shows that increasing the concentration of the Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) catalyst and the irradiation time led to an obvious increase in H<sub>2</sub> evolution. In the absence of Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80), H<sub>2</sub> was not detected from the reaction system.

In nature, the H<sub>2</sub>-generation activity of hydrogenases was first observed in *Escherichia coli*, from which the generated H<sub>2</sub> can be utilized to reduce a variety of substrates [32]. In this study, a hydrogenase mimic was, for the first time, introduced into human cancer cells for H<sub>2</sub> photogeneration, and successfully modulated intracellular ROS and pH levels. Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) nanoarchitectures with a particle size of approximately 10 nm can be internalized by cells via clathrin-mediated endocytosis [33,34]. Subsequently, the cytotoxic effects of Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) on HeLa cells after 48 h of incubation were studied using MTT assays (Fig. S4). The

results showed slight cytotoxicity to HeLa cells when the concentration of Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) reached 500 μg/mL, due to the high uptake of the nanoarchitectures into cells. The Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80)-loaded HeLa cells were further treated with blue light irradiation to catalyze intracellular hydrated proton reduction (Fig. S5). To monitor the changes in intracellular ROS levels, HeLa cells were incubated with Fenton reagent (approximately 0.15 mM) for 10 min before light irradiation [35,36]. Intracellular ROS levels were monitored by using DCHF-DA, which can be oxidized to dichlorofluorescein (DCF) by ROS. To observe the color change of DCF more accurately in living cells, the stable fluorescence intensity of MTDR (commercially available mitochondrial dye) was employed for comparison and colocalization. Fig. 4A shows that ROS-induced DCF was dispersed in the cytoplasm and nucleus. The fluorescence intensity of DCF was proportional to the amount of ROS in the cells. Without light irradiation, bright green fluorescence was observed in the HeLa cells, indicating high intracellular ROS levels. Under light irradiation, the green fluorescence intensity decreased in the Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80)-loaded HeLa cells, indicating that the photochemically generated H<sub>2</sub> reduced the ROS level in living cells. For comparison, Fenton reagent-treated HeLa cells were placed in a culture medium containing saturated molecular H<sub>2</sub> (Fig. S6). The results show that H<sub>2</sub> can reduce ROS levels, which is consistent with the findings of a previous report [8]. Although H<sub>2</sub> can be directly used to reduce ROS in living cells, it can potentially be degassed from the culture medium, resulting in an undesirable anti-ROS effect. Alternatively, H<sub>2</sub> generated by the Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80)

**Fig. 5.** Moderating pH levels in Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80)-loaded HeLa cells. Confocal images of intracellular pH measurements after cells were irradiated with blue light for (A) 0 and (B) 10 min. (C) 2,7-bis(2-carboxyethyl)-5(6)-carboxyfluorescein tetrakis(acetoxymethyl) ester (BCECF-AM) fluorescence was quantified from 100 cells of each independent experiment ( $n = 3$ ). (D) Cell viability. After ROS treatment and light irradiation, living cells were counted in view in each well with a fluorescent microscope ( $n = 3$ ). (E) Cell proliferation. The cells were treated with a Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) suspension (20 μL) and Fenton reagent (75 μM FeCl<sub>2</sub> + 150 μM H<sub>2</sub>O<sub>2</sub> + 75 μM ethylenediamine tetraacetic acid) and then irradiated by light-emitting diodes for 0–14 min. After the cells were incubated for 12 h, the number of the cells was recorded ( $n$  and  $n_0$  are the numbers of surviving cells with and without light irradiation, respectively). Scale bar: 30 μm.

nanoarchitectures can be controlled by light irradiation time and intensity.

To investigate whether photocatalytic H<sub>2</sub> can protect cells from cell death caused by ROS, the EB/AO staining technique was employed to quantify cell viability. Fig. 4B shows the morphological features of Fenton-reagent-treated HeLa cells monitored using the EB/AO technique. With an increase in the light irradiation time, uniform green live cells with normal morphology were observed, which confirms that the photochemically generated H<sub>2</sub> can reduce the oxidative stress caused by ROS. Only under the conditions of Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) and light irradiation were the ROS-treated cells protected (Fig. 4C).

The pH value of healthy cells is approximately 7.4, whereas tumor tissue exhibits acidic pH values that range from 5.7 to 7.8. Lower pH values, in the range from 4.5 to 5.5, can be found at the subcellular level, such as in late endosomes and lysosomes [37,38]. Under visible light, the Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) nanoarchitecture reduced hydrated protons to H<sub>2</sub> in HeLa cells. This may increase the pH of HeLa cells; thus, to monitor intracellular pH changes after H<sub>2</sub> generation, the pH-sensitive dye BCECF-AM was used as a local pH probe. Figs. 5A and B shows that the fluorescence intensity increased in Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80)-loaded HeLa cells after light irradiation. Furthermore, with the increased irradiation time, the intracellular fluorescence intensity increased accordingly (Fig. 5C), indicating that hydrated protons were consumed by Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) during the light irradiation. The slight fluorescence of BCECF-AM was also observed in cells without irradiation (Fig. S7). After light irradiation, the obvious increase in fluorescence intensity indicated the successful reduction of hydrated protons by Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80). The extracellular experiment also proved that the increase in pH was due to the reduction of hydrated protons to H<sub>2</sub> by Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) (Fig. S8). After light irradiation for 10 min, the pH changed from 3.8 to 6.2.

Considering that excessive ROS and an unusual pH environment may cause cellular damage and various diseases, cell viability was investigated before and after moderating the ROS and pH levels. HeLa cells were first treated with the Fenton reagent. The Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) nanoarchitectures were then incubated with HeLa cells. As shown in Fig. 5D, with different light irradiation time, the generated H<sub>2</sub> increased cell survival and vitality, indicating that H<sub>2</sub> protected the cells against ROS and/or pH-induced cell death. This phenomenon was also observed in other living cells (Fig. 5E). In particular, light irradiation treatment had the most obvious effect on the survival of HEK 293T cells compared with the other cells, including HepG2, MCF-7, and HeLa cells. After light irradiation, the number of surviving HEK 293T cells was six times larger than that of surviving cells in the absence of light irradiation. This may be because HEK 293T cells are most sensitive to ROS stress, resulting in a low cell survival ratio under ROS treatment. However, after light irradiation, cell death was suppressed due to H<sub>2</sub> generation. This shows that the Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) nanoarchitecture can protect healthy cells from oxidative stress and potentially control the deterioration of tumors.

#### 4. Conclusion

In summary, we developed a type of [FeFe]-H<sub>2</sub>ase mimic, Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80), for H<sub>2</sub> photogeneration in living cells that was capable of moderating intracellular ROS and pH levels, which were evaluated using fluorescent cell imaging methods. The Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) nanoarchitecture can be self-assembled by biocompatible polymeric pluronic F-127, catalytic [Fe<sub>2</sub>S<sub>2</sub>] sites, and photosensitizer Ru(bpy)<sub>3</sub><sup>2+</sup>. In Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80)-loaded living cells, blue light irradiation could locally promote the reduction of

hydrated protons to H<sub>2</sub>, which can function as an antioxidant to decrease ROS levels, accompanied by an increase in pH. Notably, the generated H<sub>2</sub> can increase cell survival and vitality. In summary, our study shows that Ru + Fe<sub>2</sub>S<sub>2</sub>@F127(80) can potentially be used to prevent the aggravation and deterioration of tumors caused by oxidative damage to healthy cells.
