**Abstract:** Nanoparticles have promising applications in drug delivery for cancer therapy. Herein, we prepared cationic 1,2-dioleoyl-3-trimethylammonium propane/methoxypoly (ethyl-ene glycol) (DPP) nanoparticles to deliver doxorubicin (Dox) for intravesical therapy of bladder cancer. The DPP micelles have a mean dynamic diameter of 18.65 nm and a mean zeta potential of +19.6 mV. The DPP micelles could prolong the residence of Dox in the bladder, enhance the penetration of Dox into the bladder wall, and improve cellular uptake of Dox. The encapsulation by DPP micelles significantly improved the anticancer effect of Dox against orthotopic bladder cancer in vivo. This work described a Dox-loaded DPP nanoparticle with potential applications in intravesical therapy of bladder cancer.

**Keywords:** bladder cancer, drug delivery, nanoparticles, intravesical therapy

## Introduction

Bladder cancer is one of the most common urogenital malignancies in male. In 2015, 74,000 new cases were diagnosed and 16,000 deaths occurred in the US.<sup>1</sup> The main therapeutic methods for bladder cancer are surgery, intravesical therapy, chemotherapy, and radiation therapy.<sup>2-4</sup> Among bladder cancers, non-muscle-invasive bladder cancer (NMIBC) accounts for ~70%, and can progress to muscle-invasive disease.<sup>5-7</sup> For NMIBC, a transurethral resection (TUR) of bladder tumor is followed by immediate intravesical chemotherapy. Compared to TUR alone, intravesical treatment combined with TUR shows enhanced curative effects and a prolonged TIL.<sup>8</sup> Intravesical chemotherapy following TUR has been promoted to inhibit residual microscopic tumor cells and to reduce reimplantation.<sup>9</sup> However, despite much progress has been made, intravesical chemotherapy for bladder cancer still remains to be improved. One problem is that drugs given by intravesical therapy could not efficiently penetrate the bladder tissue.<sup>10</sup> Thus, developing an efficient intravesical delivery strategy for bladder cancer therapy is a pressing need.<sup>11</sup>

Doxorubicin (Dox) is one of the most effective cytotoxic drugs used in cancer therapy.<sup>12</sup> However, cumulative cardiotoxicity and nephrotoxicity limit its clinical applications.<sup>13</sup> Compared to systemic application, drugs given by intravesical therapy mainly reach the inside of the bladder, with little-to-no effect on other organs, such as the heart, liver, spleen, lungs, kidneys, ureters, and urethra. Intravesical chemotherapy can maximize the exposure of tumor to therapeutic agents while limiting the systemic toxicity by drug due to the cavity structure of the bladder.<sup>14</sup>

In the past few years, nanoparticle delivery systems, such as 1,2-dioleoyl-3-trimethylammonium propane (DOTAP) and polyethylenimine, have been widely used for cancer therapy.<sup>15-17</sup> Nanoparticles could enhance the efficiency of drug delivery while

reducing side effects due to their distinctive properties such as more active cellular uptake and more targeted localization in tumor site.<sup>18</sup> It has also been found that nanoparticles can sustain and prolong the drug residence in the bladder by facilitating the drug penetration into the bladder mucosa.<sup>19</sup> In our study, the cationic DOTAP was used to modify the methoxypoly (ethyleneglycol) (MPEG-PLA) nanoparticles. The prepared DOTAP-MPEG-PLA (DPP) nanoparticles were characterized by size, zeta potential, morphology, and blood compatibility. The antitumor drug Dox was encapsulated into DPP micelles to form the Dox-loaded DPP (Dox/DPP) micelles formulation. The Dox/DPP micelles formulation was further characterized by size, zeta potential, morphology, and delivery efficiency. The anticancer effect of Dox/DPP micelles formulation against bladder cancer was evaluated *in vitro* and *in vivo*. Our data suggest that Dox/DPP micelles formulation has a potential application in bladder cancer therapy.

## Materials and methods

### Materials

MPEG-PLA (MPEG:PLA molar ratio =50:50, molecular weight =4,000 Da) was purchased from Jinan Daigang Bio-technology Co., Ltd. (Jinan, People's Republic of China). DOTAP (chloride salt) was purchased from Avanti Polar Lipids (Alabaster, AL, USA). Dox hydrochloride was purchased from Melonepharma (Dalian, People's Republic of China). Methanol and acetonitrile (high-performance liquid chromatography-grade) were purchased from Kermel (Tianjin, People's Republic of China). All other chemicals were at least of analytical grade. Female C57 mice (6–8 weeks old) were purchased from Beijing Hua-Fukang Biological Technology Co. Ltd. (Beijing, People's Republic of China). Mice were accustomed to the environment for at least 1 week before the experiments. All animal procedures were approved and controlled according to the guidelines of the Institutional Animal Care and Treatment Committee of Sichuan University (approval protocol number: SYXK(CHUAN)2011-178).

### Preparation of DPP micelles and Dox/DPP micelles

DPP micelles were prepared by a self-assembly method. Briefly, 98.5 mg of MPEG-PLA and 1.5 mg of DOTAP were co-dissolved in 2 mL of dichloromethane, followed by 1 hour of rotary evaporation with heat. Subsequently, 1 mL of distilled water was added followed by shaking gently in a water bath at 55°C. Finally, the prepared DPP micelles

were stored at 4°C for future use. For the preparation of Dox-loaded nanoparticles, a pH-induced self-assembly method was used according to our previous report.<sup>20</sup> Briefly, 0.1 mL of phosphate-buffered saline (PBS; 10X, pH 7.4) was added into 0.1 mL of blank DPP solution (100 mg/mL). Then, 1 mg of Dox aqueous solution (1.25 mg/mL) was added into this solution under moderate stirring. After 20 minutes, the Dox/DPP micelles were obtained and stored at 4°C for future use.

### Characterization of DPP micelles and Dox/DPP micelles

The size and zeta potential of DPP micelles and Dox/DPP micelles were determined at 25°C by Malvern Nano-ZS Instrument (Malvern Instruments, Malvern, UK). All results were the mean of three test runs.

The morphology of DPP micelles and Dox/DPP micelles was characterized by transmission electron microscope (H-6009IV; Hitachi Ltd., Tokyo, Japan). Before visualization, the nanoparticles were diluted with distilled water and placed on a copper grid covered with nitrocellulose. Samples were negatively stained with phosphotungstic acid and dried at room temperature.

High-performance liquid chromatograph (Shimadzu, Tokyo, Japan) equipped with a reverse-phase C18 column (150×4.6 mm, pore size 5 μm; Sciencelab, Tianjin, People's Republic of China) was used to measure the concentration of Dox. Chromatographic separations were performed using a mobile phase consisting of methanol, acetonitrile, and water (60:25:15, v/v/v), at a flow rate of 1.0 mL/min. Detection was carried out at 260 nm with an ultraviolet detector. The volume of each auto-injected sample was 20 μL, and the column temperature was maintained at 25°C.

The drug loading (DL) and encapsulation efficiency (EE) of Dox in the DPP micelles were determined by centrifugation ultrafiltration as follows: 0.5 mL of Dox/DPP micelles solution was placed in a centrifuge tube (molecular weight cutoff =3 kDa; Millipore, Billerica, MA, USA). The solution was then centrifuged at 10,000 rpm for 10 minutes to isolate the free Dox, and the concentration of free Dox was quantified by HPLC. Finally, the DL and EE of Dox/DPP micelles were calculated according to the following formulas:

$$DL\% = \frac{\text{Weight of drug in nanoparticles}}{\text{Total weight of nanoparticles}} \times 100 \quad (1)$$

$$EE\% = \frac{\text{Weight of drug in nanoparticles}}{\text{Weight of the drug added}} \times 100 \quad (2)$$

## In vitro drug release study

MB49 mouse urinary bladder carcinoma cell line was a generous gift from Dr Tomoko Hayashi (Moores Cancer Center, University of California, San Diego, CA, USA). The cell line was cultured in Dulbecco's Modified Eagle's Medium supplemented with 10% fetal bovine serum, penicillin (100 units/mL), and streptomycin (100 µg/mL), and maintained at 37°C in a humidified 5% CO<sub>2</sub> incubator. In vitro drug release behaviors of Dox-loaded nanoparticles or free Dox were determined by dialysis. Briefly, 2 mL of Dox/DPP micelles solution and 2 mL of free Dox solution were placed in dialysis bags (molecular weight cutoff =3.5 kDa) separately. The dialysis bags were, respectively, incubated in 20 mL phosphate buffer of pH 7.4 and 20 mL phosphate buffer of pH 5.5 at 37°C with gentle shaking. At predetermined time points, the incubation mediums were replaced with fresh incubation mediums. The amount of released drug was quantified by HPLC.

## Safety and delivery efficacy of DPP micelles

### Hematoxylin-and-eosin staining

Six- to 8-week-old mice were anesthetized with chloral hydrate (5 mg/100 mL); the dosage used was 5 mL/kg per mouse. One hundred microliters of DPP solution (10 mg/mL) was intravesically administered into the bladder and kept anesthetized for 1 hour on day 0. The mice were sacrificed, and the bladder was harvested on day 2 for hematoxylin-and-eosin staining.

### Erythrocytes aggregation in vitro

Fresh blood from Sprague Dawley rats was collected in heparinized tubes by drawing blood from rat tail. The blood was washed with normal saline (NS) until the supernatant was colorless. One hundred microliters of erythrocytes (4%) was treated with 100 µL of samples (NS, MPEG-PLA nanoparticles, or DPP micelles) in 24-well plates. After culturing for 2 hours at 37°C, images of erythrocytes were taken with an optical microscope.

### Hemolytic test in vitro

The hemolytic test of DPP micelles was carried out in vitro. Briefly, 10 mg of MPEG-PLA or DPP micelles was diluted with 1 mL of NS, and 0.5 mL of this solution was added with 0.5 mL of rat erythrocyte suspension (4%) in NS at 37°C. NS and distilled water were employed as negative and positive control, respectively. Three hours later, the erythrocyte suspension was centrifuged (1,800 rpm, 3 minutes), and the color of supernatant was compared with negative control.

Absolute achromatic supernatant solution implies that there is no hemolysis. In contrast, red supernatant solution indicates hemolysis.

### Determination of the delivery efficiency

The delivery efficiency of DPP micelles was determined in vivo. Nine female C57 mice (8 weeks old) were used to evaluate the distribution of the cargo. Nine mice were randomly divided into three groups. Coumarin-6-loaded MPEG-PLA (PP-C) nanoparticles, coumarin-6-loaded DPP (DPP-C) nanoparticles (80 µL), or NS was intravesically administered into 8-week-old female C57 mice. At different time points (1, 4, and 6 hours) after administration, mice were killed by cervical vertebra dislocation, and their bladders were immediately harvested and imaged by Bio-Real in vivo imaging system (Bio-Real Quick View 3000; Geneway International, Salzburg, Austria) using a blue filter (excitation wavelength 460–490 nm, emission 470 nm).

### Frozen section

Frozen section was used to determine the capacity of DPP micelles to enhance the permeability of instilled drugs. Coumarin-6 was encapsulated in DPP micelles as model drug. Six female C57 mice (8 weeks old) were divided into two groups, which were intravesically administered with 80 µL of PP-C or DPP-C nanoparticles. Two hours later, the mice were killed, and the bladders were harvested. The bladders were then washed with NS, followed by frozen sectioning.<sup>21</sup> The fluorescence in the bladder section was examined using a Zeiss MocBio fluorescence microscope (Zeiss, Oberkochen, Germany).

## Cellular uptake of fluorescent nanoparticles

MB49 bladder cancer cells were cultured on plates for 24 hours to achieve 60% confluence. Free coumarin-6, PP-C nanoparticles, or DPP-C nanoparticles (DL =0.5%) were added into the former plates. The concentration of coumarin-6 used was 10 ng/mL. After incubation of 2 hours, the cells were collected for measurement of coumarin-6-derived green fluorescent signal by flow cytometer.

## MTT assay for anticancer efficacy of Dox/DPP

The anticancer efficacy of Dox/DPP micelles formulation against MB49 cells was determined with MTT assay. Dox or Dox-loaded cationic nanoparticle solutions used in the cytotoxicity assays were prepared in 0.01 M PBS.

The concentrations of Dox and nanoparticles formulation were maintained in the same range throughout the cytotoxicity studies. 3,500 MB49 cells were seeded into the wells of 96-well plates. The cells were allowed to attach to the surface for 12 hours and then exposed to 100  $\mu$ L of diluted formulations ranging from 0.03125 to 8  $\mu$ g/mL. After 24 hours of incubation, 20  $\mu$ L of MTT solution (5 mg/mL) was added into the wells. Three hours later, the produced formazan crystals were dissolved by adding 100  $\mu$ L dimethyl sulfoxide. Optical densities were read at 570 nm using a microplate reader.

### Anticancer effects of Dox/DPP micelles on subcutaneous tumor model

Subcutaneous tumor model was generated via subcutaneous injection of MB49 bladder cancer cells. Six- to 8-week-old female C57 mice were injected with  $10^6$  cells on day 0. When the tumor diameter was 5 mm, 20  $\mu$ L solution of NS, free Dox, Dox-loaded MPEG-PLA (Dox/PP), and Dox/DPP (Dox 1 mg/mL) was intratumorally injected every 2 days. On day 23, six mice in each group were sacrificed, and tumors were harvested.

### Anticancer effects of Dox/DPP micelles on orthotopic bladder cancer model

Orthotopic bladder tumors were generated via injection of MB49 cells between the bladder wall and mucous layer. Briefly, 6-week-old C57 female mice were anesthetized with chloral hydrate (0.25 mg/kg). The laparotomy was performed under aseptic condition. After exposure of the bladder, 20  $\mu$ L cell suspension with  $4 \times 10^5$  cells was injected into the space between the bladder wall and mucous membrane. The tumor-bearing mice were then randomly divided into four groups. They were intravesically administered with 100  $\mu$ L solution of NS, free Dox, Dox/PP nanoparticles, or Dox/DPP micelles (Dox 1 mg/mL)

into the bladder, respectively, and kept anesthetized for 1 hour on day 0. At day 3, six mice in each group were sacrificed, and their bladders were harvested for the further evaluation.

### Statistical analysis

All experiments were performed at least three times. Results are expressed as mean  $\pm$  standard error of the mean and were analyzed by a two-tailed Student's *t*-test. *P*-values  $< 0.05$  were considered statistically significant. The analysis was conducted using GraphPad software (GraphPad Software, Inc., La Jolla, CA, USA).

### Results

Dox is a potential anticancer drug; however, cumulative cardiotoxicity and nephrotoxicity limit its clinical applications. Intravesical therapy is one of the main treatments for bladder cancer which delivers drugs into the bladder via a catheter with minimal systemic effects.<sup>17</sup> In an attempt to extend the retention time of drug in the bladder, we designed the cationic DPP micelles to encapsulate anticancer drug Dox to treat bladder cancer. The scheme is presented in Figure 1. Free Dox could not remain in the bladder to establish the effective drug concentration, while the Dox/DPP micelles could adhere to the bladder wall to prolong the drug retention because of the positive surface charge of nanoparticles. In this work, we developed the DPP drug delivery system which could effectively deliver Dox for intravesical treatment of bladder cancer.

### Preparation and characterization of DPP micelles

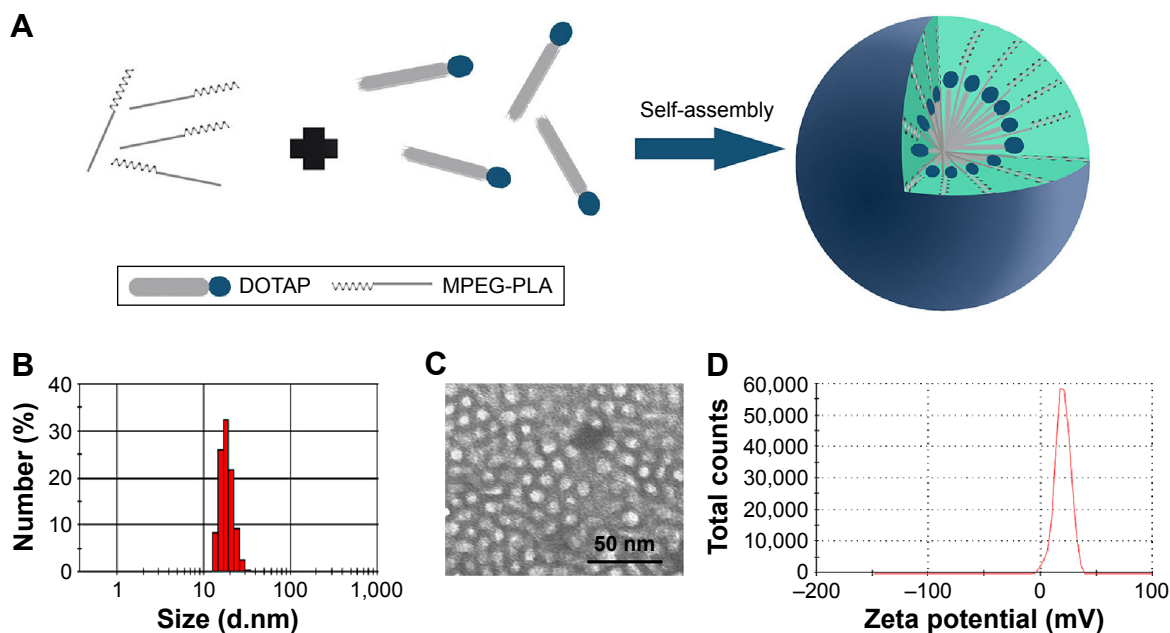

To prepare the DPP nanoparticles, a self-assembly method was used as shown in Figure 2A. MPEG-PLA diblock copolymer has an amphiphilic structure with a hydrophilic MPEG segment

**Figure 1** Schematic comparison of Dox retention in the bladder.

**Notes:** After intravesical instillation of Dox/DPP solution into the bladder, increased adhesion of Dox due to the cationic nanoparticles caused enhanced drugs retention in bladders.

**Abbreviations:** Dox, doxorubicin; Dox/DPP, Dox-loaded 1,2-dioleoyl-3-trimethylammonium propane/methoxypoly (ethyleneglycol).

**Figure 2** Preparation and characterization of DPP micelles.

**Notes:** (A) DPP micelles were prepared by self-assembly method. (B) Size distribution spectrum of DPP micelles. (C) TEM image of DPP micelles. (D) Zeta potential spectrum of DPP micelles.

and a hydrophobic PLA segment. Also, DOTAP is amphiphilic with a hydrophilic cationic head and a hydrophobic carbochain. Thus, self-assembly of MPEG-PLA and DOTAP in water allowed formation of the core-shell-structured nanoparticles. The physicochemical properties of the DPP micelles were characterized in detail. According to dynamic light-scattering results, the DPP micelles were uniform in size with a mean particle size of 18.65 nm and a polydispersity index of 0.297 (Figure 2B). The transmission electron micrographs of DPP micelles are shown in Figure 2C, which demonstrated that DPP micelles had a spherical morphology. The mean zeta potential was 19.6 mV (Figure 2D).

To further characterize the DPP micelles, we conducted the erythrocyte aggregation and hemolysis analysis to investigate the blood compatibility of MPEG-PLA and DPP micelles. As shown in Figure 3A, MPEG-PLA nanoparticles did not induce obvious erythrocyte aggregation, but DPP micelles could cause appreciable erythrocyte aggregation, indicating that cationic DPP micelles were limited in intravenous administration. Our data also showed that both MPEG-PLA and DPP micelles did not induce hemolysis (Figure 3B). In addition, the bladder did not show any symptom of edema or inflammatory reaction after treating with DPP micelles (Figure 3C). Thus, these results demonstrated a good biocompatibility of DPP micelles in the bladder.

Then, the capability of DPP micelles to deliver drug to the bladder was evaluated *in vivo*. Coumarin-6 was used as a fluorescent

model drug to be encapsulated in MPEG-PLA or DPP micelles as described previously. As shown in Figure 4A, PP-C nanoparticles could not remain in the bladder for a long time (6 hours); in contrast, DPP-C nanoparticles exhibited intense fluorescent signal over 6 hours, suggesting that DPP nanoparticles were able to prolong the residence of delivered drug in the bladder. This may be attributed to the ability of cationic nanoparticles to improve the drug retention in the bladder. In line with this finding, the frozen sections of the bladders administered with DPP-C showed stronger fluorescent signal than that of PP-C. In addition, compared to MPEG-PLA nanoparticles, DPP micelles efficiently enhanced the drug permeability into the bladder (Figure 4B) due to the positive charge that is capable of enhancing the cellular uptake and tissue absorption of nanoparticles.<sup>22</sup> Furthermore, we compared the tumor cellular uptake of DPP-C micelles with that of free coumarin-6 or PP-C nanoparticles *in vitro*. As shown in Figure 4C, MB49 bladder cancer cells preferred to uptake DPP-C rather than PP-C or free coumarin-6, implicating that the cationic surface improved the cellular uptake of nanoparticles. Thus, we conclude that the DPP nanoparticle is a potential delivery system for intravesical drug delivery.

## Preparation and characterization of Dox/DPP micelles formulation

Because DPP nanoparticle has been demonstrated to be a promising carrier for intravesical drug delivery, and Dox

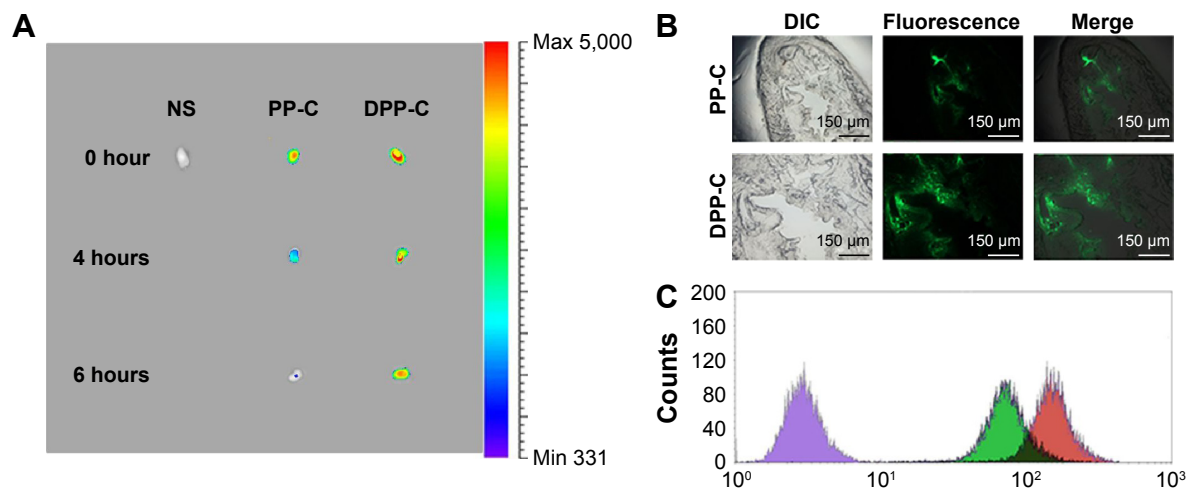

**Figure 3** Safety evaluation of DPP micelles.

**Notes:** (A) Microscopic images of erythrocyte aggregation induced by NS, MPEG-PLA nanoparticles, and DPP micelles. (B) Hemolytic test on DPP micelles. 1) distilled water (positive control); 2) MPEG-PLA; 3) DPP; 4) NS (negative control). (C) H&E staining ( $\times 100$ ) of the bladders intravesically administrated with NS and DPP micelles. **Abbreviations:** DPP, 1,2-dioleoyl-3-trimethylammonium propane/MPEG-PLA; NS, normal saline; MPEG-PLA, methoxypoly (ethyleneglycol); H&E, hematoxylin and eosin.

is a clinical drug for the treatment of bladder cancer, we made further efforts to develop Dox/DPP micelles for the treatment of bladder cancer. Dox was loaded into the blank DPP micelles by a pH-induced self-assembly method. To our knowledge, the solubility of Dox in distilled water is high, while Dox cannot be well dissolved in PBS. Therefore, when Dox aqueous solution was dropped into DPP micelles in PBS (pH 7.4) under stirring, the Dox became hydrophobic and

self-assembled into the hydrophobic cores of DPP micelles (Figure 5A). We found that Dox could be encapsulated into DPP micelles efficiently with a drug encapsulation efficiency of  $\sim 89.75\%$  and a drug loading of  $\sim 8.47\%$ . This method of preparing Dox/DPP micelles was simple and easy to scale up, implying its advantage in practical application.

We characterized physicochemical properties of Dox/DPP micelles. According to dynamic light-scattering results, the

**Figure 4** Efficiency of DPP micelles in intravesical delivery of cargo.

**Figure 5** Preparation and characterization of Dox/DPP micelles.

**Notes:** (A) Synthesis of Dox/DPP micelles. (B) Size distribution spectrum of Dox/DPP micelles. (C) TEM image of Dox/DPP micelles. (D) Release profile of free Dox and Dox/DPP micelles at pH 5.5 and 7.4. For all graphs, error bars indicate mean  $\pm$  SEM;  $n=3$  independent experiments.  $**P<0.01$  (Student's *t*-test).

**Abbreviations:** Dox/DPP, Dox-loaded 1,2-dioleoyl-3-trimethylammonium propane/methoxy poly (ethylene glycol); TEM, transmission electron microscopy; Dox, doxorubicin; SEM, standard error of the mean; NPs, nanoparticles.

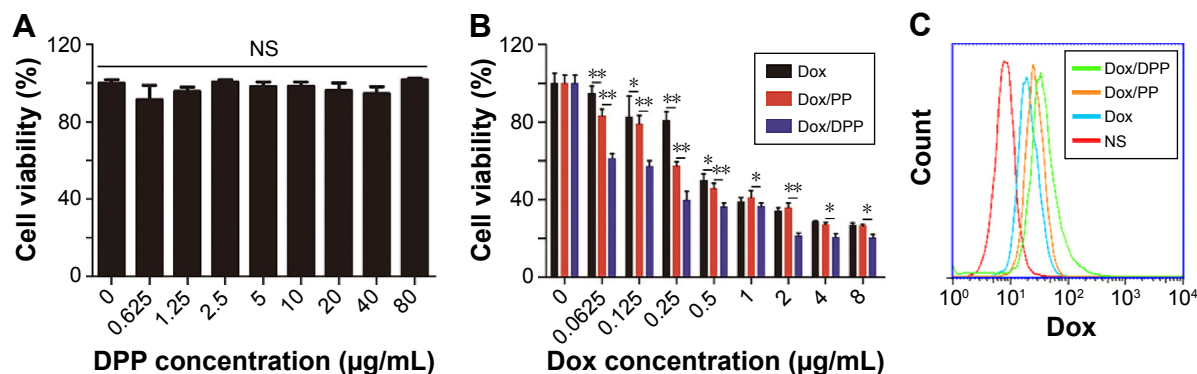

Dox/DPP micelles were monodispersed with a mean particle size of 18.71 nm (Figure 5B), suggesting no obvious changes in size and morphology caused by Dox loading. The transmission electron micrographs of Dox/DPP micelles are shown in Figure 5C. Additionally, we investigated the release profile of Dox from Dox/DPP micelles *in vitro* by dialysis. As shown in Figure 5D, the nanoparticles obviously slowed down the release of Dox. Similar to Tomar et al's report,<sup>23</sup> the mechanism of Dox release from the DPP micelles can be divided into two phases: a burst-release phase and a controlled-release phase. The burst release corresponded to the Dox adsorbed or attached by weak bonding onto the surface of the nanoparticles, while the controlled release was due to the entrapment of nanoparticles. Meanwhile, we found that Dox was released faster in a condition of pH 5.5 than pH 7.4 (Figure 5D). The protonation of the amino group of Dox at lower pH might account for the pH-dependent releasing behavior.<sup>24</sup> Therefore, it was anticipated that Dox could achieve slow release in plasma under normal physiological condition (pH 7.4) but quick release at the slightly acidic tumor site (pH 5.5).

### Anticancer effect of Dox/DPP micelles

To study the cytotoxicity of Dox/DPP micelles in bladder cancer cells, we first examined whether drugs can be delivered

into living cells by DPP micelles using flow cytometry. Next, we investigated the cytotoxicity of Dox/DPP micelles in MB49 bladder cancer cells. As expected, blank DPP micelles had no obvious cytotoxicity against MB49 cells even at relatively high concentrations (Figure 6A), whereas Dox/DPP micelles markedly inhibited cell viability (Figure 6B) with a relative low  $IC_{50}$  value of 0.281  $\mu\text{g/mL}$ , compared with free Dox ( $IC_{50}$  0.815  $\mu\text{g/mL}$ ) or Dox/PP nanoparticles ( $IC_{50}$  0.638  $\mu\text{g/mL}$ ) result from the enhanced drug uptake (Figure 6C). Next, we used mouse subcutaneous tumor model to evaluate the anticancer effect of Dox/DPP micelles *in vivo*. As shown in Figure 7A and B, compared with Dox administration alone, treatment of Dox/DPP micelles inhibited bladder tumor growth as evidenced by reduced tumor volume and decreased tumor weight.

To corroborate the anticancer effect of Dox/DPP micelles *in vivo*, we established the orthotopic bladder cancer model by injecting MB49 bladder cancer cells and administered Dox/DPP micelles intravesically. Our results indicated that blank DPP micelles and free Dox showed no apparent influence on the bladder tumor growth; this may be indicating that free Dox is unable to permeate into the bladder mucosa to kill the tumor cells. In contrast, Dox loaded on DPP micelles showed significant inhibition of tumor size and repression of tumor weight (Figure 7C and D). Taken together, our results

**Figure 6** Anticancer effect of Dox/DPP micelles in vitro. **Notes:** (A) Cytotoxicity of DPP micelles. (B) Cytotoxicity of free Dox and Dox/PP and Dox/DPP micelles. (C) MB49 cellular uptake of free Dox (blue), Dox/PP nanoparticles (orange), Dox/DPP micelles (green), and NS (red). For all graphs, error bars indicate mean  $\pm$  SEM; n=3 independent experiments. \* $P$ <0.05 and \*\* $P$ <0.01 (Student's  $t$ -test). **Abbreviations:** Dox/DPP, Dox-loaded DPP; DPP, 1,2-dioleoyl-3-trimethylammonium propane/methoxypoly (ethylene glycol); Dox/PP, Dox-loaded methoxypoly (ethylene glycol); NS, normal saline; SEM, standard error of the mean; Dox, doxorubicin.

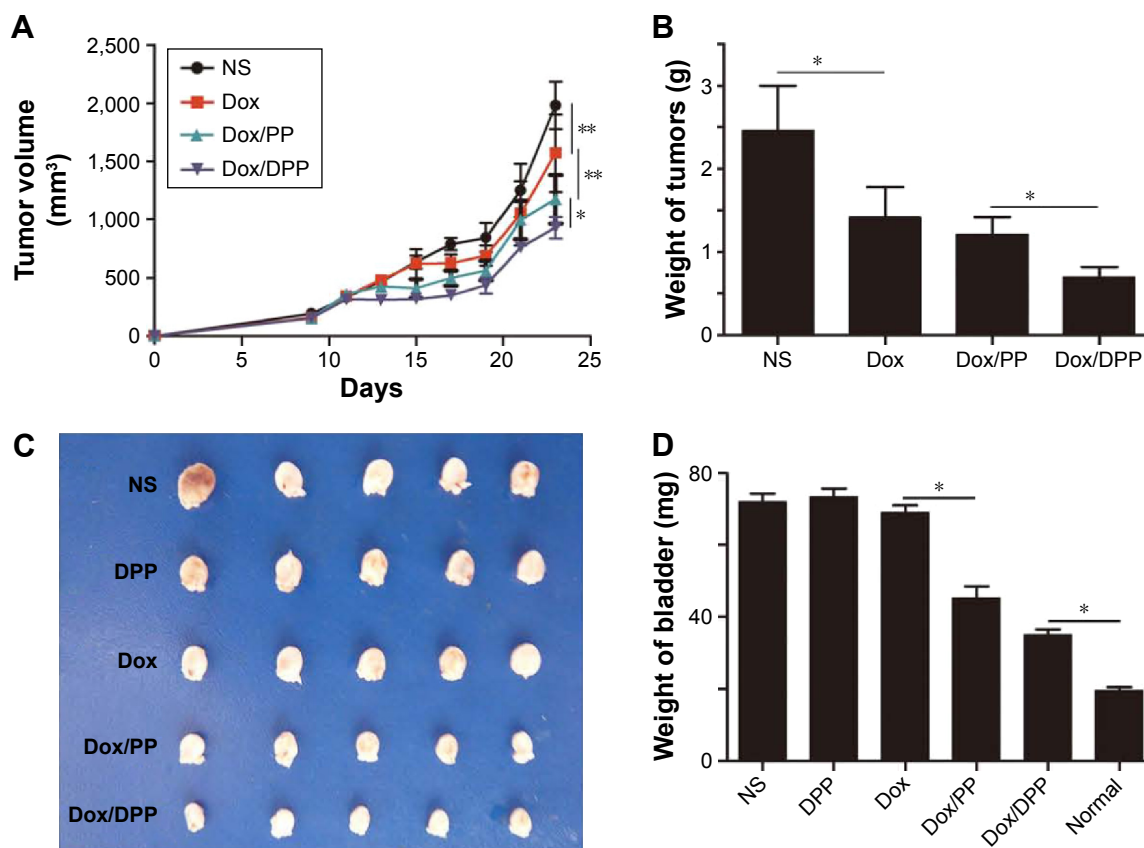

suggested that DPP micelles can effectively deliver Dox into the bladder for the treatment of bladder cancer.

### Discussion

In this work, we prepared the cationic DPP nanoparticles to encapsulate the antitumor drug Dox to form the Dox/DPP

nanoassemblies formulation. This study suggested that Dox may have potential applications in bladder cancer therapy and the Dox/DPP formulation may represent a candidate for intravesical therapy of bladder cancer.

Cationic nanoparticles has called much attention for their wide application as delivery system.<sup>25,26</sup> For example,

**Figure 7** Anticancer effects in vivo. **Notes:** (A) Tumor growth curve in subcutaneous tumor model. (B) Tumor weight in subcutaneous tumor model. (C) Image of tumors in each treatment group in orthotopic bladder tumor model. (D) Weight of tumor-bearing bladders in each orthotopic bladder tumor model treatment group. The normal group is the bladder not bearing tumor. For all graphs, error bars indicate mean  $\pm$  SEM; n=3 independent experiments. \* $P$ <0.05 and \*\* $P$ <0.01 (Student's  $t$ -test). **Abbreviations:** SEM, standard error of the mean; NS, normal saline; Dox, doxorubicin; Dox/PP, Dox-loaded methoxypoly (ethylene glycol); Dox/DPP, Dox-loaded DPP; DPP, 1,2-dioleoyl-3-trimethylammonium propane/methoxypoly (ethylene glycol).

Wang et al tried to co-deliver paclitaxel and an interleukin-12-encoded plasmid by cationic core-shell nanoparticles to suppress the cancer growth;<sup>27</sup> Liu et al used an amphiphilic peptide to prepare cationic nanoparticles that acted as an efficient antimicrobial agent.<sup>28</sup> Despite extensive applications as delivery system, the development of cationic nanoparticles is still challenged by the fast elimination by reticuloendothelial system. Intravesical administration of cationic nanoparticles has shows significant potency in NMIBC treatment, since the topical administration minimizes the risk of erythrocytes aggregation and protects the cationic nanoparticles from being cleared away by the reticuloendothelial system. Hence, we developed the cationic DPP micelles for intravesical delivery of Dox to treat bladder cancer. The hybrid nanoparticles had a size of 20 nm and a surface charge of 20 mV. These physical characters were preferred by cells or tissues compared to large neural or negative nanoparticles, resulting in an enhanced cellular uptake of nanoparticles. Moreover, our results indicated that the cationic nanoparticles could help improve the retention and penetration of drugs. Thus, the cationic DDP nanoparticles could serve as an efficient delivery system for intravesical drug delivery.

Apart from the advantage of efficient delivery, it has been demonstrated that cationic DPP micelles are safe for intravesical administration. The DDP nanoparticles comprise biocompatible materials namely MPEG-PLA and DOTAP, both of which were approved by the US Food and Drug Administration as therapeutic agents. In addition, the results of both hemolysis analysis and hematoxylin-and-eosin staining indicated their safety, since the DPP micelles did not cause hemolysis, inflammation, edema, or other adverse reaction.

In the present study, DPP micelles were employed for intravesical delivery of Dox, which is a highly potent anti-tumor drug approved for clinical use against bladder cancer. However, the long-term clinical use of Dox is compromised by its severe toxicity, the most serious being irreversible cardiomyopathy and subsequent congestive heart failure.<sup>29</sup> Fortunately, the strategies involving nanoparticles and topical administration could play a positive role in limiting the cardiac toxicity of Dox. By topical administration of Dox/DPP micelles to the bladder, the Dox level was increased in the bladder, and meanwhile, the cardiotoxicity of Dox was shunned (data not shown). Moreover, the drug release profile showed that Dox/DPP micelles were capable of sustaining the drug concentration in the tumor site, while the free Dox exhibited a robust release. Additionally, our in vivo results showed that Dox/DPP micelles could suppress the growth of bladder cancer. Our results were also supported by Bilensoy et al's research, in which the cationic nanoparticles delivered

mitomycin C to bladder tumor site and improved the therapeutic effect of mitomycin C in the bladder.<sup>30</sup> Therefore, the Dox/DPP micelles formulation shows a promising application in intravesical treatment of bladder cancer.

## Conclusion

We prepared cationic DPP nanoparticles for intravesical drug delivery. These nanoparticles can improve the retention, penetration, and intracellular uptake of cargos. Then encapsulation of Dox in DPP micelles significantly enhanced its anticancer effect against bladder cancer in vitro and in vivo. The DPP micelle-encapsulated Dox might have potential applications in intravesical therapy of bladder cancer.

## International Journal of Nanomedicine

### Publish your work in this journal

The International Journal of Nanomedicine is an international, peer-reviewed journal focusing on the application of nanotechnology in diagnostics, therapeutics, and drug delivery systems throughout the biomedical field. This journal is indexed on PubMed Central, MedLine, CAS, SciSearch®, Current Contents®/Clinical Medicine,

Submit your manuscript here: <http://www.dovepress.com/international-journal-of-nanomedicine-journal>

Dovepress

Journal Citation Reports/Science Edition, EMBase, Scopus and the Elsevier Bibliographic databases. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
