*These authors contributed equally to this work

Background: The aim of the present study was to investigate the association between tumor necrosis factor-alpha (TNF- α) gene G-238A polymorphism and risk of coronary artery disease (CAD) using a meta-analytical approach.

Methods: The PubMed and Embase databases were searched for relevant publications up to January 13, 2015. Four authors (XPH, XDZ, XTZ, and ZJZ) independently selected the studies, extracted, and analyzed the data using the Comprehensive Meta-Analysis software. The sensitivity and subgroups analyses were also performed. Either a fixed effects or a random effects model was used to estimate pooled odds ratios (ORs) and their 95% confidence intervals (CIs).

Results: Finally, ten articles including eleven case-control studies involving 4,222 patients and 4,832 controls were yielded. The results indicated no significant association between G-238A polymorphism and CAD risk (A vs G: OR = 1.08, 95% CI = 0.89–1.30; AA vs GG: OR = 1.15, 95% CI = 0.59–2.25; GA vs GG: OR = 1.14, 95% CI = 0.88–1.48; AA vs [GG + GA]: OR = 1.09, 95% CI = 0.56–2.14; (GA + AA) vs GG: OR = 1.11, 95% CI = 0.90–1.38). In the subgroup analyses, similar results were obtained with overall populations. The sensitivity analyses showed that the overall results were robust. No publication bias was detected.

Conclusion: Based on current evidence, we can conclude that TNF- α G-238A polymorphism might not be associated with CAD risk.

Keywords: tumor necrosis factor-alpha, TNF- α , polymorphism, coronary artery disease, coronary heart disease, meta-analysis

Introduction

Tumor necrosis factor-alpha (TNF- α) is an inflammatory mediator that plays important roles in inflammatory and immune responses.¹ Several single-nucleotide polymorphisms (SNPs) have been identified in the TNF- α promoter.² Of these SNPs, conversion from guanine (G) to adenine (A) in the promoter at position-308 (rs1800629) and -238 (rs361525) has been intensively studied for these allelic variations showing functional significance.^{3,4} Many studies have identified that the TNF- α G-308A and/or G-238A are associated with many human diseases,^{5–8} including coronary artery disease (CAD).^{9,10} Of these diseases, the association between these two polymorphisms and some diseases were identified via a meta-analytical approach, from which inconsistent results can be pooled from original studies and a more precise results can be provided.¹¹

CAD is also named as ischemic heart disease or coronary heart disease, mainly including stable angina pectoris, unstable angina pectoris, and myocardial infarction.^{12,13} Serum levels of TNF- α are elevated in patients with CAD and might modify the risk for developing CAD events since it affects endothelial cell hemostatic function.¹⁴ Hence,

we can hypothesize that TNF- α gene polymorphisms might be involved in the CAD susceptibility. In 1998, Herrmann et al performed a case-control study in France and Northern Ireland population, and the results showed that the TNF- α gene G-308A and G-238A polymorphisms were unlikely to contribute to CAD risk in an important way.¹⁵ Since then, many epidemiological studies have been published and inconsistent results have been revealed. The association between TNF- α G-308A polymorphism and CAD risk has been investigated by three published meta-analyses.^{9,10,16} In contrast, there is no meta-analysis on the association between TNF- α gene G-238A polymorphism and CAD risk until now. Therefore, we conducted this meta-analysis to study the overall correlation between the G-238A polymorphism and CAD susceptibility.

Materials and methods

This meta-analysis was reported according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement.¹⁷ As meta-analysis is a secondary analysis, ethical approval is not necessary.

Eligibility criteria

According to the PICOS¹⁸ approach, the publication was considered eligible if it met all the following criteria: 1) the patient was clearly diagnosed with CAD, coronary heart disease, ischemic heart disease, stable angina pectoris, unstable angina pectoris, myocardial infarction, or other CAD variants; 2) the exposure was the presence of G-238A polymorphism in the TNF- α gene; 3) the control group was healthy population or volunteers without coronary heart disease manifestations, either from hospital or community; 4) the outcome was the incidence of CAD, either fatal or nonfatal; and 5) the study was used a case-control design. Moreover, the information essential for calculating odds ratios (ORs) and relevant 95% confidence intervals (CIs) should be provided. We chose the most comprehensive report if duplicate publication or overlapped information was identified.

Information sources

The PubMed and Embase databases were searched for relevant publications up to January 13, 2015. Keywords were coronary heart disease, coronary artery disease, ischemic heart disease, angina pectoris, angina, acute coronary syndrome, myocardial infarction, myocardial infarct, polymorphism, and tumor necrosis factor or TNF. References of recent reviews, previous meta-analyses, and eligibility

studies were also manually scanned. Table S1 shows the search strategy used for the PubMed.

Data collection

Two authors (XPH and ZJZ) independently retrieved and selected studies for inclusion according to the aforementioned eligibility criteria. Then these two authors extracted the following data from the included studies: the last name of first author and publication year, country of origin and ethnicity, endpoints of CAD, polymorphism, sample size of cases and controls, source of controls, genotype distribution of cases and controls, genotyping method, and Hardy–Weinberg equilibrium (HWE) for control. HWE was tested by χ^2 test at the 50% significance level. Disagreements were resolved by discussion.

Data analysis

The ORs and corresponding 95% CIs were calculated to summarize the pooled effect sizes for G-238A polymorphism. All possible genetic models, the allelic model (A vs G), dominant model ([AG + AA] vs GG), codominant model (AA vs GG, AG vs GG), and recessive model (AA vs [AG + GG]) were used to estimate the overall relationship.

First, the heterogeneity was quantitatively evaluated using the I^2 statistic.¹⁹ An I^2 value no larger than 25% indicates the absence of heterogeneity, so the fixed effects model was suggested; otherwise, the random effects model was used. The subgroup analysis was performed to investigate the source of heterogeneity and the difference between different ethnicities and HWE. The sensitivity analysis was conducted by sequential omission of individual studies to assess the influence of overall results.²⁰ The funnel plot and Egger's test were used to detect the publication bias.²¹ All the analyses were conducted using the Comprehensive Meta-Analysis software (version 2.2; Biostat, Englewood, NJ, USA).^{22,23}

Results

Study selection

The flowchart of study selection process is shown in Figure 1. A total of 253 publications were identified initially, and 175 publications were selected for further screening after removing duplicate records. After titles or abstracts were screened, a total of 59 articles preliminarily met the inclusion criteria. Four potential eligible articles were excluded because they were published in Russian and full texts could not be accessed.^{24–27} Two case-control studies identified in one article¹⁵ were considered as independent studies. From four articles^{28–31} with overlapped population, two articles^{28,30}

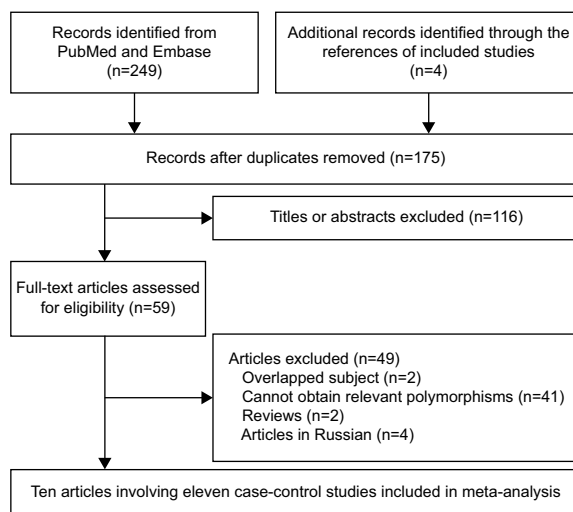

Figure 1 Flowchart of study section in the meta-analysis.

presenting more comprehensive information were included. Finally, ten articles with eleven case-control studies were included in this meta-analysis.^{15,32–40}

Study characteristics

Eleven case-control studies involving 4,222 cases and 4,832 controls investigated G-238A polymorphism.^{15,32–40} There were five studies based on Caucasian population^{15,32,33,35} and six studies concerning Asian population.^{34,36–40} Three of these studies were out of HWE.^{37–39} All controls were healthy population, eg, healthy visitors of patients, healthy volunteers,

healthy blood donors, or outpatients confirmed negative by cardiac assessment. Table 1 shows the main characteristics of all the included studies.

Meta-analysis

Of the eligible eleven case-control studies, one study⁴⁰ reported significant association; in contrast, the other ten studies demonstrated that the association was nonsignificant (Figure 2). The overall results of five genetic models all identified nonsignificant association between G-238A polymorphism and CAD risk (A vs G: OR =1.08, 95% CI =0.89–1.30, $I^2=34.33\%$, Figure 2; AA vs GG: OR =1.15, 95% CI =0.59–2.25, $I^2=0\%$; GA vs GG: OR =1.14, 95% CI =0.88–1.48, $I^2=54.34\%$; AA vs [GG + GA]: OR =1.09, 95% CI =0.56–2.14, $I^2=0\%$; [GA + AA] vs GG: OR =1.11, 95% CI =0.90–1.38, $I^2=41.92\%$).

After being stratified by ethnicity, the results of Asian and Caucasian populations were similar to that of the overall population. The studies in HWE also revealed nonsignificant association. Table 2 shows the overall and subgroup analyses results of G-238A polymorphism and CAD risk. The sensitivity analysis showed that none of the included eleven studies dramatically influenced the pooled results under all the five genetic models (Figure 3).

Publication bias

The funnel plots (Figure 4) and Egger's test demonstrated that there was no publication bias in our meta-analysis ($P=0.28$ for

Discussion

CAD remains the major cause of mortality and morbidity worldwide. Smoking, diabetes, hypertension, obesity,

family history, stress, hyperlipidemia, and alcohol abuse were considered the conventional risk factors of CAD; however, these conventional factors can only explain 50% of the total risk factors of CAD cases.⁴¹⁻⁴⁷ Genetic factors might contribute to the other half of the total risk factors, and many polymorphisms are considered to be associated with the onset and development of CAD.^{12,46,48-51} Our meta-analysis focused on the TNF- α gene promoter G-238A polymorphism and revealed that this polymorphism was not associated with CAD risk. In the subgroup analyses, similar results with overall population were obtained, and the sensitivity analyses showed that the overall results were robust.

There were ten publications with eleven case-control studies focusing on the G-238A polymorphism and CAD risk in our meta-analysis. According to the result of literature search, our meta-analysis is the first meta-analysis on the G-238A polymorphism. Similar to G-308A polymorphism,^{9,10,16} our result also revealed a nonsignificant association between G-238A polymorphism and risk of CAD. We also performed subgroup analysis to investigate the effects of ethnicity and HWE. Only Asian and Caucasian populations were adopted. The subgroup analysis revealed no association for Asian population, Caucasian population, and the studies in HWE. Considering the interesting phenomenon of G-308A polymorphism,^{9,10,16} the G-238A polymorphism included small number of studies and needs further research. In other words, the current result is not the final result.

Figure 3 Forest plot of sensitivity analysis by omitting a single study each time of overall population of TNF- α G-238A polymorphism and CAD risk (A vs G model). **Notes:** Herrmann I 1998, the study conducted in Northern Ireland; Herrmann F 1998, the study conducted in France. **Abbreviations:** TNF- α , tumor necrosis factor-alpha; CAD, coronary artery disease; CI, confidence interval.

For this polymorphism, how many new studies should be conducted in the future remains a question. Based on current evidence, we could not judge whether the sample size was sufficient for decisive conclusion. Moreover, whether significant correlation between G-238A polymorphism and risk of CAS exists in other ethnicity, such as Africans or Turks, remains unclear. Also, the polymorphism associated with patients with CAD and concomitant diseases, such as periodontal disease,⁵² also needs to be examined in further researches. Moreover, our meta-analysis also provides some clinical implications. We knew that, the personalized drug treatment is involved in the genetic background. Hence, development of a special drug for patients with CAD with G-238A polymorphism is not needed. However, the clinicians should advise their patients with this polymorphism to have peace of mind and not to take this polymorphism as a risk factor in the clinical work.

TNF- α G-238A polymorphism might not be considered for the genetic diagnosis of CAD.

Obviously, heterogeneity was large in three genetic models. Mild heterogeneity detected in certain genetic models and subgroup analyses was only partially explained by ethnicity and HWE (Table 2). The heterogeneity is common in meta-analysis of genetic association studies,^{23,53-55} and we should not ignore it since pooled results may be influenced by heterogeneity. Therefore, the substantial heterogeneity was one limitation of our meta-analysis. Second, as all the included studies were limited within Asians or Caucasians, our conclusion may not be reasonably extrapolated for other ethnic groups. Third, the sample size from eligible studies was not enough. The small sample size might influence the result. Although we tried our best to collect all the relevant studies, certain publications published in languages other

Figure 4 Funnel plot of standard error by log odds ratio for detection publication bias of G-238A polymorphism (A vs G model).

than English or Chinese were excluded because of inaccessibility to the full text and/or impenetrability due to language barriers. Hence, although the test for publication bias revealed no publication bias in our meta-analysis, the bias that originated from publication bias should not be ignored. Fourth, for lacking original data of gene–gene and gene–environmental interactions and adjusted conventional risk factors, we could not further evaluate potential gene–gene and gene–environmental interactions based on adjusted ORs. Finally, for lacking appropriate methodological quality tool,¹¹ we did not assess the risk of bias of included studies. Hence, current results based on unadjusted data may be confounded to the pooled effect.

Conclusion

In conclusion, there was no evidence suggesting that TNF- α G-238A polymorphism was associated with the risk of CAD. The nonsignificant results were without ethnic difference. Due to the limitations and implications of current meta-analysis, we suggest that further well-designed studies with large sample size should be conducted to clarify the association between the polymorphisms and CAD risk, among which meta-analysis of genome-wide association studies⁵⁶ is the best.

Therapeutics and Clinical Risk Management

Dovepress

Publish your work in this journal

Therapeutics and Clinical Risk Management is an international, peer-reviewed journal of clinical therapeutics and risk management, focusing on concise rapid reporting of clinical studies in all therapeutic areas, outcomes, safety, and programs for the effective, safe, and sustained use of medicines. This journal is indexed on PubMed Central, CAS,

EMBASE, Scopus and the Elsevier Bibliographic databases. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <http://www.dovepress.com/therapeutics-and-clinical-risk-management-journal>
