Correspondence e-mail: gsnichol@email.arizona.edu

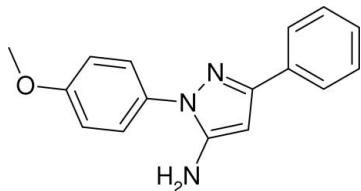

Received 21 April 2009; accepted 25 April 2009

Key indicators: single-crystal X-ray study;  $T = 296\text{ K}$ ; mean  $\sigma(\text{C}-\text{C}) = 0.002\text{ \AA}$ ;  $R$  factor = 0.044;  $wR$  factor = 0.111; data-to-parameter ratio = 15.9.

The synthesis of the title compound,  $\text{C}_{16}\text{H}_{15}\text{N}_3\text{O}$ , is regiospecific and single-crystal X-ray diffraction provides the only means of unambiguous structural analysis, with the benzene ring bonded to the imine C atom. The phenyl ring and the essentially planar (r.m.s. deviation 0.0354 Å) methoxybenzene group are rotated by 29.41 (5) and 37.01 (5)°, respectively, from the central pyrazole ring. An intermolecular N—H···N hydrogen bond links symmetry-related molecules into a  $C(5)$  chain, which runs parallel to the  $b$  axis.

**I. R. Kumarasinghe, V. J. Hruby and G. S. Nichol**

#### **Comment**

It has been pharmacologically shown that co-administration of opioids with cyclooxygenase (COX) inhibitors is synergistic and reduces development of drug tolerance (Raffa, 2001; Ossipov *et al.*, 2004). The creation of bifunctional molecules having both COX2 inhibitory activity and Opioid mu agonist activity is a promising approach to retain better analgesic properties. We are investigating plausible COX2 pharmacophores that can be obtained for bifunctional design using known organic reactions. Based on the evidence so far (Joshi *et al.*, 1979; Gavrin *et al.*, 2007) we probed whether the reaction between hydrazine derivatives and benzoylacetone will usefully yield pyrazoles as a product substituted with 1,5-vicinal diaryls, which is an important structural feature for COX2 inhibitory activity (Michaux & Charlier, 2004). We observed that the reaction between benzoylacetone with 2-(4-methoxyphenyl)hydraziniumchloride is regiospecific which means it provides solely 1-(4-methoxyphenyl)-3-phenyl-1*H*-pyrazol-5-amine, (I), which is undesired for our purpose. Furthermore it cannot be correctly identified with one-dimensional nuclear Overhauser effect or two-dimensional heteronuclear multiple bond correlation spectroscopic methods, leaving single-crystal X-ray diffraction as the only possible means of unambiguous identification of the compound.

The molecular structure of (I) is shown in Figure 1. Two regioisomers were possible and here the structure is unambiguous with the phenyl ring (C11-C16) bonded to the imine carbon atom C1. Molecular dimensions are unexceptional. The methoxybenzyl group is essentially planar (r.m.s. deviation of a mean plane fitted through C4 to C10 and O is 0.0354 Å) and is rotated by 37.01 (5)° from the central pyrazole ring. The phenyl ring (C11-C16) is rotated by 29.41 (5)° from the central pyrazole ring. A lone N–H···N hydrogen bond links the molecules into a C(5) chain which runs parallel to the *b* axis (Figure 2).

#### **Experimental**

Benzoylacetone (1.45 g, 10 mmol) in 50 ml of absolute ethanol was treated with 2-(4-methoxyphenyl) hydrazinium-chloride (1.75 g, 10 mmol) under reflux for 1 day. The solvent was then removed by rotary evaporation and the residue was extracted with a 1:1 mix of dichloromethane and H<sub>2</sub>O. The organic layer was separated and dried with anhydrous MgSO<sub>4</sub>, filtered and then the solvent removed by rotary evaporation to leave a brown residue. This was washed with hexane and recrystallized from dichloromethane. C<sub>16</sub>H<sub>15</sub>N<sub>3</sub>O, (I), yield = 90%. TOF MS EI m/z 264.9839. <sup>1</sup>H NMR (CDCl<sub>3</sub>)δ 3.85 (s, 3H), 5.95 (s, 1H), 7.0 (d, 2H), 7.25 (m, 1H), 7.4 (t, 2H) 7.5 (d, 2H), 7.8 (d, 2H) <sup>13</sup>CNMR (CDCl<sub>3</sub>) δ 55.50, 87.59, 114.61, 125.522, 126.049, 127.626, 128.391, 131.463, 133.551, 145.740, 151.043, 158.971

#### **Refinement**

Amine hydrogen atoms were freely refined. Aryl hydrogen atoms were refined with  $U_{\text{iso}}(\text{H}) = 1.2 U_{\text{eq}}(\text{C})$  and a fixed C–H distance of 0.93 Å; methyl hydrogen atoms were refined with  $U_{\text{iso}}(\text{H}) = 1.5 U_{\text{eq}}(\text{C})$  and a fixed C–H distance of 0.96 Å.

### Refinement

Refinement on $F^2$	Secondary atom site location: difference Fourier map
Least-squares matrix: full	Hydrogen site location: difference Fourier map
$R[F^2 > 2\sigma(F^2)] = 0.044$	H atoms treated by a mixture of independent and constrained refinement
$wR(F^2) = 0.111$	$w = 1/[\sigma^2(F_o^2) + (0.048P)^2 + 0.671P]$
	where $P = (F_o^2 + 2F_c^2)/3$

$S = 1.02$	$(\Delta/\sigma)_{\max} = 0.001$
3019 reflections	$\Delta\rho_{\max} = 0.20 \text{ e \AA}^{-3}$
190 parameters	$\Delta\rho_{\min} = -0.15 \text{ e \AA}^{-3}$
Primary atom site location: structure-invariant direct methods	Extinction correction: none

### Special details

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) etc. and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
