Abstract

The Panel on Food Additives and Flavourings of the European Food Safety Authority was requested to consider in this revision 2 of Flavouring Group Evaluation 201, the additional data on genotoxicity submitted by the Industry on two substances, 2-methylpent-2-enal [FL-no: 05.090] and 2-methylcrotonaldehyde [FL-no: 05.095], from subgroup 1.1.2 of FGE.19. In FGE.201Rev1, the Panel concluded that further data were required in order to clarify the genotoxic potential of this subgroup and considered the testing of 2-methylcrotonaldehyde [FL-no: 05.095] in a comet assay in liver and duodenum, the first site of contact, as a preferred option to further investigate the genotoxicity *in vivo*. New genotoxicity studies have been submitted for both 2-methylpent-2-enal [FL-no: 05.090] and 2-methylcrotonaldehyde [FL-no: 05.095]. 2-Methylpent-2-enal [FL-no: 05.090] tested in a combined micronucleus/comet assay did not induce DNA damage, overruling the weak gene mutation effect observed in bacteria and confirming the negative results observed in the *in vitro* micronucleus assay. 2-Methylcrotonaldehyde [FL-no: 05.095] did not induce gene mutations in liver and glandular stomach of transgenic rats. In addition, 2-methylcrotonaldehyde [FL-no: 05.095] tested in an *in vivo* comet assay in liver and duodenum, it did not induce DNA damage. Overall, the Panel concluded that the genotoxic evidence observed *in vitro*, was not confirmed *in vivo* for the representative substances 2-methylcrotonaldehyde [FL-no: 05.095] and 2-methylpent-2-enal [FL-no: 05.090], therefore all the 10 substances in this subgroup [FL-no: 02.174, 05.033, 05.090, 05.095, 05.105, 05.107, 05.126, 07.261, 12.065 and 12.079] can be evaluated through the Procedure for the evaluation of flavouring substances.

1. Introduction

1.1. Background and Terms of Reference as provided by the requestor

The use of flavouring is regulated under Regulation (EC) No 1334/2008¹ of the European Parliament and Council of 16 December 2008 on flavourings and certain food ingredients with flavouring properties for use in and on foods. On the basis of Article 9(a) of this Regulation, an evaluation and approval are required for flavouring substances.

The Union List of flavourings and source materials was established by Commission Implementing Regulation (EC) No 872/2012². The list includes a number of flavouring substances for which the safety evaluation should be completed in accordance with Commission Regulation (EC) No 1565/2000³.

The substances in this group were included in the Union list with a footnote 1 (under evaluation by EFSA).

In its opinion about this subgroup of 2012, the EFSA Panel considered that the mutagenicity hazard could not be cleared by the endpoints evaluated in the *in vivo* micronucleus assay submitted. The Panel therefore conclude that further data were required in order to clarify the genotoxic potential of this subgroup. The Panel considered the Comet assay with [FL-no: 05.095] as test material and performed on liver, blood and first site of contact, as a preferred option to further investigate the genotoxicity *in vivo*.

The additional data submitted by the applicant consist essentially of:

- a transgenic mutation assay in combination with an *in vivo* micronucleus assay for the substance 2-methylcrotonaldehyde [FL-no: 05.095];
- a combination of a Comet/micronucleus assay for the substance 2-methylpent-2-enal [FL-no: 05.090].

The Panel also considered in this opinion on FGE.201 rev.1 that the additional data on 2-methylcrotonaldehyde [FL-no: 05.095] could also be considered representative for the following substances: 2,8-dithianon-4-en-4-carboxaldehyde [FL-no: 12.065] and 2-(methylthiomethyl)but-2-enal [FL-no: 12.079].

1.1.1. Terms of Reference

The European Commission requests the European Food Safety Authority (EFSA) to evaluate the new information submitted on 2-methylpent-2-enal [FL-no: 05.090] and 2-methylcrotonaldehyde [FL-no: 05.095] including also 2,8-dithianon-4-en-4-carboxaldehyde [FL-no: 12.065] and 2-(methylthiomethyl)but-2-enal [FL-no: 12.079] and, depending on the outcome, proceed to the full evaluation of the substances of this group listed in the table below, in accordance with Commission Regulation (EC) No 1565/2000, within 9 months.

In case the genotoxic potential cannot be ruled out or the procedure cannot be applied, EFSA is asked to characterise the hazards and also quantify the exposure.

As regards the substance 2,6-Dimethyl-2,5,7-octatriene-1-ol acetate ([FL-no: 09.931] CAS no 999999-91-4) the applicant indicate that it is included in this subgroup 1.1.2 of FGE19 (FGE.201). However, this substance has been already evaluated by EFSA in FGE 207 and FGE 72 Rev.1 of 2013.

As regards substance 4-methyl-3-hepten-5-one ([FL-no: 07.261] CAS no 22319-31-9) EFSA indicated in its opinion FGE.204 that 'the 2-methyl substituted alpha, beta-unsaturated aldehydes in FGE.201Rev1 can be considered as structurally related to it [FL-no: 07.261]. Thus the final conclusion on [FL-no: 07.261] will be drawn based on the outcome of the evaluation of FGE.201Rev1'.

2. Data and methodologies

2.1. History of the evaluation of FGE.19 substances

Flavouring Group Evaluation 19 (FGE.19) contains 360 flavouring substances from the EU Register being α,β -unsaturated aldehydes or ketones and precursors which could give rise to such carbonyl substances via hydrolysis and/or oxidation (EFSA, 2008a).

The α,β -unsaturated aldehyde and ketone structures are structural alerts for genotoxicity (EFSA, 2008a). The Panel noted that there were limited genotoxicity data on these flavouring substances but that positive genotoxicity studies were identified for some substances in the group.

The α,β -unsaturated carbonyls were subdivided into subgroups on the basis of structural similarity (EFSA, 2008a). In an attempt to decide which of the substances could go through the Procedure, a (quantitative) structure-activity relationship ((Q)SAR) prediction of the genotoxicity of these substances was undertaken considering a number of models that were available at that time (DEREKfW, TOPKAT, DTU-NFI-MultiCASE Models and ISS-Local Models (Gry et al., 2007)).

The Panel noted that for most of these models internal and external validation has been performed, but considered that the outcome of these validations was not always extensive enough to appreciate the validity of the predictions of these models for these α,β -unsaturated carbonyls. Therefore, the Panel considered it inappropriate to totally rely on (Q)SAR predictions at this point in time and decided not to take substances through the procedure based on negative (Q)SAR predictions only.

The Panel took note of the (Q)SAR predictions by using two ISS Local Models (Benigni and Netzeva, 2007a,b) and four DTU-NFI MultiCASE Models (Gry et al., 2007; Nikolov et al., 2007) and the fact that there are available data on genotoxicity, *in vitro* and *in vivo*, as well as data on carcinogenicity for several substances. Based on these data the Panel decided that 15 subgroups (1.1.1, 1.2.1, 1.2.2, 1.2.3, 2.1, 2.2, 2.3, 2.5, 3.2, 4.3, 4.5, 4.6, 5.1, 5.2 and 5.3) (EFSA, 2008b) could not be evaluated through the Procedure due to concern with respect to genotoxicity. Corresponding to these subgroups, 15 Flavouring Group Evaluations (FGEs) were established: FGE.200, 204, 205, 206, 207, 208, 209, 211, 215, 219, 221, 222, 223, 224 and 225.

For 11 subgroups, the Panel decided, based on the available genotoxicity data and (Q)SAR predictions, that a further scrutiny of the data should take place before requesting additional data from the Flavouring Industry on genotoxicity. These subgroups were evaluated in FGE.201, 202, 203, 210, 212, 213, 214, 216, 217, 218 and 220. For the substances in FGE.202, 214 and 218, it was concluded that a genotoxic potential could be ruled out and accordingly these substances were evaluated using the Procedure. For all or some of the substances in the remaining FGEs, FGE.201, 203, 210, 212, 213, 216, 217 and 220 the genotoxic potential could not be ruled out.

To ease the data retrieval of the large number of structurally related α,β -unsaturated substances in the different subgroups for which additional data are requested, EFSA worked out a list of representative substances for each subgroup (EFSA, 2008c). In selecting the representative substances, expert judgement was applied. In each subgroup, the representative substances were selected taken into account chain length, branched chain, lipophilicity and possible additional functional groups. Likewise, an EFSA genotoxicity expert group has worked out a test strategy to be followed in the data retrieval for these substances (EFSA, 2008b).

The Flavouring Industry has been requested to submit additional genotoxicity data according to the list of representative substances and test strategy for each subgroup.

The Flavouring Industry has now submitted additional data and the present FGE concerns the evaluation of these data requested on genotoxicity.

2.2. Presentation of the substances in flavouring group evaluation 201Rev2

The FGE.201, originally, concerned 11 substances, which are presented in Appendix A, Table A.1. The 11 substances correspond to subgroup 1.1.2 of FGE.19 (EFSA, 2008b). Eight of these substances are aliphatic acyclic 2-alkylated α,β -unsaturated aldehydes with or without additional double bonds [FL-no: 05.033, 05.090, 05.095, 05.105, 05.107, 05.126, 05.130 and 05.178] and three are precursors for such aldehydes [FL-no: 02.174, 09.177 and 09.931].

A summary of their current evaluation status by the JECFA is given in Appendix B, Table B.1 (JECFA, 2004, 2007).

The α,β -unsaturated aldehyde and ketone structures are structural alerts for genotoxicity (EFSA, 2008b). Accordingly, the available data on genotoxic or carcinogenic activity for the eight aldehydes in FGE.201 [FL-no: 05.033, 05.090, 05.095, 05.105, 05.107, 05.126, 05.130 and 05.178] and the two aldehydes [non-Register substances, 2,6-dimethyl-2,5,7-octatrienal and 2-methyl-2-propenal, see Table A.1] anticipated to be metabolism products formed from two of the three precursors in FGE.201 [FL-no: 02.174, 09.177 and 09.931], have been considered in FGE.201. The anticipated metabolism product formed from the third precursor [FL-no: 02.174] is one of the eight Register aldehydes in this FGE [FL-no: 05.095].

The Panel has also taken into consideration the outcome of the predictions from five selected (Q) SAR models (Benigni and Netzeva, 2007a; Gry et al., 2007; Nikolov et al., 2007) on the 10 aldehydes [FL-no: 05.033, 05.090, 05.095, 05.105, 05.107, 05.126, 05.130, 05.178, 2-methyl-2-propenal and 2,6-dimethyl-2,5,7-octatrienal]. The 10 aldehydes and their (Q)SAR predictions are shown in Appendix C Table C.1.

After the publication of FGE.201, Industry withdrew their wish of maintaining three of the substances for use as flavours in EU, [FL-no: 05.130, 05.178 and 09.177]. One substance, [FL-no: 09.931], was evaluated in FGE.207 (EFSA CEF Panel, 2013) where the genotoxicity concern was ruled out. In FGE.204 (EFSA CEF Panel, 2012a), the Panel noted that 2-methyl substituted α,β -unsaturated aldehydes in FGE.201 can be considered as structurally related to 4-methyl-3-hepten-5-one [FL-no: 07.261]. Thus, the conclusion on [FL-no: 07.261] will be drawn based on the outcome of the evaluation of FGE.201Rev2.

In FGE.201Rev1 (EFSA CEF Panel, 2012b), the Panel considered that additional data required for 2-methylcrotonaldehyde [FL-no: 05.095] could also be considered representative for the substances in FGE.225, 2,8-dithianon-4-en-4-carboxaldehyde [FL-no: 12.065] and 2-(methylthiomethyl)but-2-enal [FL-no: 12.079].

Therefore, substances evaluated in FGE.201Rev2 are [FL-no: 02.174, 05.033, 05.090, 05.095, 05.105, 05.107, 05.126, 07.261, 12.065 and 12.079]. New genotoxicity data on [FL-no: 05.095] are considered to cover the genotoxicity concern for the other nine substances [FL-no: 02.174, 05.033, 05.090, 05.105, 05.107, 05.126, 07.261, 12.065 and 12.079].

2.3. History of the evaluation of the substances belonging to FGE.201

In FGE.201 (EFSA, 2009), the Panel concluded that additional genotoxicity data were required for all 11 α,β -unsaturated aldehydes and alcohols and related esters considered in the FGE.

In the EFSA Opinion 'List of α,β -unsaturated aldehydes and ketones representative of FGE.19 substances for genotoxicity testing' (EFSA, 2008c), representative flavouring substances have been selected for subgroup 1.1.2, corresponding to FGE.201, for which additional data on genotoxicity were requested, according to the Opinion of the Panel on the 'Genotoxicity Test Strategy for Substances Belonging to Subgroups of FGE.19' (EFSA, 2008b) (see Table 1).

In reply to a data request presented in FGE.201, additional data were provided by Industry (EFTA, 2011) for the representative substance 2-methylpent-2-enal [FL-no: 05.090] and a non-representative substance, also from subgroup 1.1.2, 2-methylcrotonaldehyde [FL-no: 05.095]. No data were submitted for the other representatives identified by EFSA (EFSA, 2008c), beta-sinensal [FL-no: 05.178], 2-methyl-2-propenal (not a Register substance but a precursor for such) or its precursor

2-methylallyl butyrate [FL-no: 09.177]. According to Industry, [FL-no: 05.178 and 09.177] are not any longer supported by the Industry and accordingly no data were submitted for these substances due to the lack of test material for the required genotoxicity testing. Also, alpha-sinensal [FL-no: 05.130] is not any longer supported by the Industry. Data submitted were evaluated in FGE.201 Revision 1 (FGE.201Rev1).

Table 1: Representative substances for subgroup 1.1.2 of FGE.19 (EFSA, 2008c)

FL-no JECFA-no	EU register name	Structural formula	Comments
05.090 1209	2-Methylpent-2-enal		Originally selected as representative substance
05.095 1201	2-Methylcrotonaldehyde		Representative substance for all the substances in FGE.201Rev2
05.178 1227	Beta-Sinensal		Originally selected as representative substance Not supported by industry
Not in the EU Register	2-Methyl-2-propenal or its precursor [09.177]		Originally selected as representative substance
09.177 1207	2-Methylallyl butyrate		Originally selected as representative substance Not supported by industry

In FGE.201Rev1 (EFSA CEF Panel, 2012b), the Panel concluded that there is some evidence for [FL-no: 05.095] and an indication for [FL-no: 05.090] to show a potency for the induction of gene mutations *in vitro*. Furthermore, the Panel considered that the mutagenicity hazard could not be cleared by the endpoints evaluated in the *in vivo* micronucleus assay and that further data are required in order to clarify the genotoxic potential of this subgroup. A comet assay performed with [FL-no: 05.095] in liver, blood and first site of contact was considered as a preferred option to further investigate the genotoxicity *in vivo*. Finally, the Panel concluded that the genotoxicity data for [FL-no: 05.095] could be representative for [FL-no: 02.174, 05.033, 05.090, 05.105, 05.107, 05.126, 07.261, 12.065 and 12.079] but not for the remaining substances of this subgroup [FL-no: 05.130, 05.178, 09.177 and 09.931], for which however, an evaluation by the Panel is not needed any longer.

In response to the requested genotoxicity data in FGE.201Rev1 on representative substances for subgroup 1.1.2, new data on 2-methylpent-2-enal [FL-no: 05.090] and 2-methylcrotonaldehyde [FL-no: 05.095] have been submitted by Industry that are evaluated in the present revision of FGE.201 (FGE.201Rev2).

The new data submitted for [FL-no: 05.090 and 05.095] are described and evaluated in Section 3 of the present revision FGE.201Rev2. Sections 2.4 and 2.5 report the same information that was presented in FGE.201 (EFSA, 2009) and FGE.201Rev1 (EFSA CEF Panel, 2012b), respectively.

FGE	Adopted by EFSA	Link	No. of Substances
FGE.201	25 September 2008	http://www.efsa.europa.eu/en/efsajournal/pub/1080	11
FGE.201Rev1	24 May 2012	http://www.efsa.europa.eu/en/efsajournal/pub/2749	11

2.4. Data evaluated by the Panel in FGE.201⁴

2.4.1. (Q)SAR Predictions

In Appendix C Table C.1, the outcomes of the (Q)SAR predictions for possible genotoxicity activity in five *in vitro* (Q)SAR models (ISS-Local Model-Ames Test, DTU-NFI-MultiCASE-Ames test, -Chromosomal aberration test in Chinese hamster ovary cells (CHO), -Chromosomal aberration test in Chinese hamster lung cells (CHL) and -Mouse Lymphoma Test) are presented. For the three short-chain aldehydes [FL-no: 05.095, 05.090 and 05.105], the predictions in the ISS Local Ames test

⁴ The data presented in Section 2.4 are cited from the Scientific Opinion FGE.201. These data are the basis for the conclusions in FGE.201 requesting additional genotoxicity data.

(TA100) were positive. For 2-methyl-2-propenal, the DTU-NFI-MultiCASE Ames test was positive. All other predictions were either negative or out of domain (See Table C.1).

2.4.2. Carcinogenicity studies

No carcinogenicity studies are available for the eight α,β -unsaturated aldehydes and the α,β -unsaturated aldehydes anticipated to be formed from the three precursors [FL-no: 02.174, 09.177 and 09.931] in subgroup 1.1.2.

2.4.3. Genotoxicity studies

Only one study on 2-methylpent-2-enal [FL-no: 05.090] and one study on 2-methyl-2-propenal [not in Register] is available for the eight aldehydes and the α,β -unsaturated aldehydes anticipated to be formed from the precursors in subgroup 1.1.2. The study on 2-methylpent-2-enal is a spot test (Florin et al., 1980), which is not in accordance with the OECD guideline. Furthermore, the methods and results are insufficiently reported and the study is considered to be of insufficient validity. The study on 2-methyl-2-propenal (and the structurally related 2-propyl and 2-butyl substituted 2-propenals), in Ames test in *Salmonella* Typhimurium strain TA100, showed mutagenic effects of all the 2-alkylated 2-propenals (Eder and Deininger, 2001). The study was found valid. See Appendix D Table D.1.

2.4.4. Conclusion on genotoxicity

The genotoxicity concern with respect to this group of substances due to the presence of an α,β -unsaturated aldehyde group (or precursor for this) cannot be ruled out based on the genotoxicity data and (Q)SAR predictions available.

2.4.5. Conclusion

The Panel concluded that a genotoxic potential of the 11 α,β -unsaturated aldehydes and alcohols and related esters in the present FGE.201 could not be ruled out. Accordingly the 11 substances cannot be evaluated through the Procedure. Additional data on genotoxicity on substances representative for this subgroup should be provided according to the Genotoxicity Test Strategy for Substances Belonging to Subgroups of FGE.19 (EFSA, 2008b).

2.5. Additional genotoxicity data evaluated by the Panel in FGE.201Rev1⁵

2.5.1. *In Vitro* data

2.5.1.1. Ames tests

2-Methylpent-2-enal [FL-no: 05.090] was tested in *S. Typhimurium* strains TA98, TA100, TA102, TA1535 and TA1537 in the presence and absence of metabolic activation by S-9 (Bowen, 2011). In the first experiment performed using plate incorporation methodology, concentrations of 1.6, 8, 40, 200, 1,000 and 5,000 $\mu\text{g}/\text{plate}$ were assessed for all tester strains. Evidence of toxicity was only observed in strains TA1537 at 5,000 $\mu\text{g}/\text{plate}$ in the presence of S-9 and TA102 at 1,000 $\mu\text{g}/\text{plate}$ and above in the presence of S-9. The concentration range was therefore narrowed for a second experiment. In addition, the second experiment included a supplementary S-9 pre-incubation step for the S-9 treatment group to increase the range of assay detection. Following these treatments, evidence of toxicity was observed in the presence of S-9 in *S. Typhimurium* strains TA98, TA100, TA1535 and TA102 at 2,500 $\mu\text{g}/\text{plate}$ and above and in strain TA1537 at 1,250 $\mu\text{g}/\text{plate}$ and above. Toxicity was not observed in the absence of S-9. In the second experiment, at a single intermediate dose of 2,500 $\mu\text{g}/\text{plate}$ without S-9 treatment in strain TA1537, there was a small (2.1-fold), statistically significant increase in revertants, but this was not dose-related and was within the range of historical controls. The Panel concluded that 2-methylpent-2-enal was not mutagenic in this study (Tables D.1 and D.4).

A bacterial reverse mutation assay was also conducted in *S. Typhimurium* strains TA98, TA100, TA1535, TA1537, and *Escherichia coli* strain WP2uvrA with 2-methylcrotonaldehyde [FL-no: 05.095] (Nakajima, 2006a), which does not belong to the substances selected as representative by the

⁵ The data presented in Section 2.5 are cited from the Scientific Opinion FGE.201Rev1. These data are the basis for the conclusions in FGE.201Rev1 requesting additional genotoxicity data.

Panel for this subgroup. In an initial experiment, the concentrations used were 8.19, 20.5, 51.2, 128, 320, 800, 2,000 and 5,000 µg/plate. In strain TA100, 2-methylcrotonaldehyde increased the number of colonies showing reverse mutations, both with and without metabolic activation by S-9, in a dose-dependent manner. In the absence of S-9, the increases were threefold from 320 to 5,000 µg/plate, and with S-9 metabolic activation, the increases were up to 3.9-fold from 320 to 2,000 µg/plate; under these conditions, growth inhibition was observed at 5,000 µg/plate. In all other strains, in the presence and absence of metabolic activation treatment with 2-methylcrotonaldehyde did not result in an increase of reverse mutant colony (Tables D.1 and D.3).

In a second experiment using 2-methylcrotonaldehyde [FL-no: 05.095] concentrations of 156, 313, 625, 1,250, 2,500 and 5,000 µg/plate, treatment of strain TA100 in the absence of S-9 activation induced a dose-dependent increase in reverse mutant colonies (1.5- to 7.2-fold), with growth inhibition observed at 5,000 µg/plate in the absence of S-9. In the presence of S-9, treatment of strain TA100 also gave a dose-dependent (313–2,500 µg/plate) increase in reverse mutant colonies (1.2- to 4.6-fold), with growth inhibition again observed at 5,000 µg/plate. In the absence of S-9, strain TA1535 gave a 1.8-fold increase in reverse mutants at 2,500 µg/plate, but this was not dose-dependent. Strain TA98 had a nearly twofold increase in reverse mutant colonies in the absence of S-9 at both 2,500 and 5,000 µg/plate. These increases were above the historical control range but they were not clearly dose-related. In the presence of S-9, the same strain showed a 1.5-fold increase at 5,000 µg/plate. *E. coli* strain WP2uvrA showed a twofold increase in reverse mutant colonies at 5,000 µg/plate treatment without S-9 which was above the historical control range, but otherwise there was no increase at any other dose or with S-9 treatment (Tables D.1 and D.3).

Strain WP2uvrA did not show evidence of mutagenicity in the first experiment but produced weakly mutagenic results in the second experiment at the highest concentration tested. Since the repeatability of the result was not confirmed, an additional experiment with this strain was performed from 156 to 5,000 µg/plate and this resulted in a 1.4-fold increase in revertant colonies at 2,500 and 5,000 µg/plate. The Panel considered these small increases as indication for a weak mutagenic potential because the effects were reproducible in two out of three experiments and were above the historical control range. However, with the exception of strain TA100, there were no increases in reverse mutation colonies exceeding that of the negative control by twofold. The Panel considered that 2-methylcrotonaldehyde [FL-no: 05.095] was mutagenic in the TA100 strain in the absence and presence of S-9 under the specified conditions of the assay.

In order to clarify the ability of 2-methylcrotonaldehyde [FL-no: 05.095] to induce reverse mutations and provide cross-laboratory comparison of results, a third Ames assay was conducted (Ballantyne, 2011) in the same laboratory in which the Bowen 2011 study was performed. In order to directly compare 2-methylcrotonaldehyde with 2-methylpent-2-enal, the latter was tested additionally in this assay. Both substances were tested in the single *S. Typhimurium* strain TA100, in the absence and the presence of metabolic activation, in three separate experiments.

The first experiment was conducted using final concentrations of 2-methylcrotonaldehyde [FL-no: 05.095] and 2-methylpent-2-enal [FL-no: 05.090] at 1.6, 8, 40, 200, 1,000 and 5,000 µg/plate in strain TA100 with or without S-9. Following these treatments, no evidence of toxicity was observed. Statistically significant ($p < 0.01$) increases in revertants were observed for 2-methylcrotonaldehyde at 5,000 µg/plate in the absence of S-9 metabolic activation (1.3-fold) and at all concentrations tested in the presence of S-9. In all cases, the increases were small versus concurrent controls (1.2- to 1.7-fold vs concurrent controls) but were above the range of historical controls. Similarly, for 2-methylpent-2-enal, small statistically significant ($p < 0.05$) increases in revertants (1.2-fold) were observed at 5,000 µg/plate in the absence of S-9 metabolic activation and at 1.6, 200 and 5,000 µg/plate ($p < 0.01$) in the presence of S-9. In all cases, the increases were small versus concurrent controls (1.2- to 1.4-fold vs concurrent controls) but the results obtained in the presence of S-9 were above the range of historical controls and dose-related (Tables D.1 and D.5).

In the second experiment, treatment of strain TA100 with 2-methylcrotonaldehyde [FL-no: 05.095] and 2-methylpent-2-enal [FL-no: 05.090] was performed in the absence and in the presence of S-9 at narrowed concentration intervals. 2-Methylcrotonaldehyde and 2-methylpent-2-enal were assayed at 51.2, 128, 320, 800, 2,000 and 5,000 µg/plate in the absence of S-9 using plate incorporation methodology and 8.192, 20.48, 51.2, 128, 320, 800, 2,000 and 5,000 µg/plate in the presence of S-9 using both plate incorporation and pre-incubation methodology. Clear evidence of toxicity was only observed following pre-incubation methodology treatments with 2-methylcrotonaldehyde in the presence of S-9 at 5,000 µg/plate and pre-incubation methodology treatments with 2-methylpent-2-enal in the presence of S-9 at 2,000 and 5,000 µg/plate. In the absence of S-9 activation, small but

statistically significant increases in revertant colonies showing a dose-dependent relationship were observed for 2-methylcrotonaldehyde at 800, 2,000 and 5,000 µg/plate. These were only 1.3- to 1.4-fold over concurrent vehicle controls but above the range of historical controls. In the presence of S-9 activation, 2-methylcrotonaldehyde showed a small but statistically significant increase in revertant colonies only at 5,000 µg/plate using plate incorporation (1.4-fold) and at 800 and 2,000 µg/plate using pre-incubation methodology (1.7-fold). These increases were above the historical control range. Similarly, in the presence of S-9 activation 2-methylpent-2-enal showed a small (1.4-fold) but statistically significant increase in revertants only at 5,000 µg/plate using plate incorporation methodology, but in contrast gave no increases in revertant colonies using pre-incubation. In the absence of S-9 activation, a statistically significant increase in revertant colonies was observed at 5,000 µg/plate that was 2.5-fold over concurrent vehicle controls. These increases were above the historical control range, likewise (Tables D.1 and D.5).

In order to further investigate the reproducibility and dose relationship of some increases in revertant numbers seen in the first two experiments, a third experiment was performed with 2-methylcrotonaldehyde [FL-no: 05.095] in the presence of S-9 (plate incorporation methodology only) and with 2-methylpent-2-enal in the absence of S-9. In order to investigate the dose range over which the increases in revertant numbers were previously observed, treatment concentration ranges of 0.32–5,000 µg/plate and 51.2–5,000 µg/plate were employed for 2-methylcrotonaldehyde and 2-methylpent-2-enal, respectively. Following these treatments, no evidence of toxicity was observed with both substances. For 2-methylcrotonaldehyde, small (1.3- to 1.8-fold) but statistically significant and dose-related increases in revertants were observed at 1,000 and 5,000 µg/plate. These increases were above the historical control range. For 2-methylpent-2-enal, a small but statistically significant increase in revertants was observed at 5,000 µg/plate. This increase was only 1.3-fold vs. concurrent vehicle controls but above the historical control range.

Overall, statistically significant increases in revertant numbers (when the data were analysed at the 1% level using the Dunnett's test) were observed in the absence and presence of S-9 in each experiment where the TA100 strain was treated with 2-methylcrotonaldehyde [FL-no: 05.095]. These increases provided evidence of a dose relationship, with the exception of the first experiment in the absence of S-9, where the largest increase was observed at the lowest treatment concentration (1.6 µg/plate) and was attributed to an aberrant occurrence that was not reproduced in subsequent experiments. While the magnitude of these increases were small (1.3- to 1.8-fold above the concurrent control levels), these data were considered by the authors of the study report as evidence of 2-methylcrotonaldehyde mutagenic activity in strain TA100 in the absence and presence of metabolic activation with S-9. The Panel noted that these increases, although being small, were above the range of historical controls and that these effects were generally reproducible in the different experiments of this study. Thus, the Panel concluded that this study provided an indication for a weak mutagenic activity of 2-methylcrotonaldehyde [FL-no: 05.095] in the presence and absence of metabolic activation.

2-Methylpent-2-enal [FL-no: 05.090] treatments of strain TA100 in the absence and presence of S-9, assayed simultaneously for comparison to 2-methylcrotonaldehyde, resulted in statistically significant increases in revertant numbers in the absence and presence of S-9 in each experiment, with the exception of experiment 2 using pre-incubation methodology in the presence of S-9. The maximum treatment concentration in the experiment 2 in the absence of S-9 resulted in a statistically significant increase of 2.5-fold over the concurrent control level, though this was not reproduced in experiments 1 or 3, nor previously observed (Bowen, 2011). However, the small increases observed in experiments 1 and 3 were statistically significant and above the range of historical controls. Thus, there is at least some consistency in these three experiments. The authors of the study report (Ballantyne, 2011) noted that all of the observed increases provided at least some evidence of dose dependence (in most cases the only responding concentration being the highest treatment concentration), and were reproducible over most of the treatment occasions. Accordingly, the authors considered that these increases are indicative of weak 2-methylpent-2-enal mutagenic activity in strain TA100 in the absence and in the presence of S-9 in this assay system. The Panel agreed with the authors.

The details and conclusions for the Ames tests described above are summarised in Tables D.1 and D.3–D.6.

2.5.1.2. *In vitro* Micronucleus assay

2-Methylpent-2-enal [FL-no: 05.090] was evaluated in an *in vitro* micronucleus assay in human peripheral blood lymphocytes for its ability to induce chromosomal damage or aneuploidy in the presence

and absence of rat liver metabolic activation system (S-9) as an *in vitro* metabolising system (Whitwell, 2011). Cells were stimulated for 48 h with phytohaemagglutinin to produce exponential cell growth followed by treatment for 3 h (with a 21 h recovery period) in the presence or absence of S-9 or 24 h treatment with no recovery in the absence of S-9. In the first experiment, doses of 0, 100, 200 and 300 µg/mL of 2-methylpent-2-enal were tested. Frequencies of micronucleated binucleate (MNBN) cells were not significantly different ($p \leq 0.05$) from that of the negative control in all conditions with the exception of the highest concentration analysed post 3 + 21 h without S-9 treatment (300.0 µg/mL, inducing 49% cytotoxicity, mean MNBN cells 1.05%). This increase, although statistically significant relative to the concurrent vehicle control, was relatively small and did not exceed the range of historical controls (0.1–1.2% MNBN cells). Furthermore, both replicate cultures at this concentration and all other 2-methylpent-2-enal concentrations analysed were within a normal range of MNBN cell values.

To clarify these data, a 3 + 21 h treatment in the absence of S-9 was performed in a second experiment with 100.0, 175.0, 260.0 and 300.0 µg/mL concentrations of 2-methylpent-2-enal. Statistically significant increases in micronucleated cell frequencies were not observed. Consistent with current regulatory guideline recommendations for this assay, the maximum concentrations that were analysed induced between 49% and 57% cytotoxicity. The Panel agreed with the authors of the study report and concluded that 2-methylpent-2-enal did not induce micronuclei in cultured human peripheral blood lymphocytes following treatment in the absence and presence of metabolic activation with S-9 (Table D.1).

2.5.1.3. *In vitro* chromosomal aberration assay

The ability of 2-methylcrotonaldehyde [FL-no: 05.095] to induce chromosomal aberrations was evaluated in an *in vitro* assay using Chinese hamster pulmonary fibroblasts (Nakajima, 2006b). Microscopic observations were conducted during the chromosome aberration tests using short-term treatment with three or four different doses respectively, 105, 210 and 421 µg/mL in the absence of S-9 and 105, 210, 421 and 841 µg/mL in the presence of S-9. The frequencies of chromosome structural aberrations as a result of short-term treatment of 2-methylcrotonaldehyde without metabolic activation by S-9 were 0.5% in the negative control, 3.5% in the 105 µg/mL treatment, 12.0% in the 210 µg/mL treatment, 55% in the 421 µg/mL treatment and 50.0% in the mitomycin positive control. The appearance of polyploidy cells was not observed at any dose and there were no significant reductions in relative cell growth rate under these test conditions. In the presence of S-9, the frequencies of chromosome structural aberration as a result of treatment using 2-methylcrotonaldehyde were 0.05% in the negative control, 1.5% in the 105 µg/mL dose, 1.5% in the 210 µg/mL dose, 33.0% in the 421 µg/mL dose, 96.5% in the 841 µg/mL dose and 39% in the cyclophosphamide positive control treatment group. The frequencies of appearance of polyploidy cells were equivalent to those of the negative control group at all doses and there was no significant reduction in relative cell growth rate. Therefore, a dose-dependent induction of structural chromosome aberrations was associated with 2-methylcrotonaldehyde treatment in both short-term treatments with and without S-9 under testing conditions. An increase in numerical chromosomal aberrations was not observed. The Panel agreed with the authors of the study report and concluded that 2-methylcrotonaldehyde induced chromosomal aberrations in cultured mammalian cells in the presence and absence of metabolic activation (Table D.1).

2.5.2. *In vivo* genotoxicity tests

2.5.2.1. Micronucleus assay

2-Methylcrotonaldehyde [FL-no: 05.095] was tested in an *in vivo* micronucleus assay using BDF1 male mice (Nakajima, 2007). Five mice per group were administered by oral gavage with a dose of 2-methylcrotonaldehyde once per day for two consecutive days at either 250, 500 or 1,000 mg/kg bw (1,000 mg/kg bw was the maximum tolerable dose based on an initial dose-finding study in which two out of three animals died after administration of 2,000 mg/kg bw). The bone marrow cells were sampled 24 h after the second dosing. Administration of 2-methylcrotonaldehyde resulted in one case of piloerection 25 h after the first administration of 1,000 mg/kg. No other treatment groups showed any sign of toxicity by means of visual examination or by body weight loss. There was no statistically significant increase in the frequency of micronucleated erythrocytes in treated groups compared to the negative control group. The ratio of polychromatic erythrocytes (PCE) among total erythrocytes was not changed. Thus, the exposure of the bone marrow to the test substance could not be demonstrated based on that parameter. However, since mortality was observed at a dose of 2,000 mg/kg bw in the dose-finding study, the Panel considered that systemic availability of the test substance could be

assumed at the highest dose of 1,000 mg/kg bw in the micronucleus assay. Although, it may be assumed that the bone marrow was exposed to the test substance since the bone marrow is a well-perfused tissue, no convincing evidence was provided. The Panel considered the study to be compliant with OECD guideline 474 except that no justification for the use of a single sex was given in the report, i.e. no data demonstrating that there are no substantial differences between sexes in toxicity. It was concluded that 2-methylcrotonaldehyde did not induce micronuclei in mice bone marrow cells (Table D.2).

2.5.3. Discussion of the additional data

2-Methylpent-2-enal [FL-no: 05.090] and 2-methylcrotonaldehyde [FL-no: 05.095] were tested in a series of *in vitro* tests to explore their genotoxicity potential.

For 2-methylcrotonaldehyde [FL-no: 05.095], there is some evidence for a mutagenic activity in the presence and absence of metabolic activation. This is based on two reliable studies on the induction of bacterial gene mutations (Nakajima, 2006a; Ballantyne, 2011) with the first study providing clear evidence for mutagenic activity and the latter study providing indication for a weak mutagenic activity.

For the representative substance 2-methylpent-2-enal [FL-no: 05.090], there is an indication for a weak mutagenic activity both in the presence and absence of metabolic activation. This indication is based on the results of one reliable study (Ballantyne, 2011) and structural similarity with 2-methylcrotonaldehyde [FL-no: 05.095].

In vitro assessment of micronucleus induction by 2-methylpent-2-enal in the presence and absence of S-9 metabolic activation was negative. In the case of 2-methylcrotonaldehyde, a dose-dependent induction of structural, but not numerical chromosomal aberrations *in vitro* was observed, both with and without S-9. To further investigate the clastogenic potential an *in vivo* micronucleus assay using BDF1 male mice was performed and no evidence of clastogenic effects was identified but the respective test was inconclusive. These data support the absence of clastogenicity for the two substances 2-methylpent-2-enal [FL-no: 05.090] and 2-methylcrotonaldehyde [FL-no: 05.095].

However, since there is some evidence for 2-methylcrotonaldehyde [FL-no: 05.095] and an indication for 2-methylpent-2-enal [FL-no: 05.090] to show a potency for the induction of gene mutations *in vitro* the Panel considered the mutagenicity hazard not cleared by the endpoints evaluated in the *in vivo* micronucleus assay. The Panel therefore concluded that further data are required in order to clarify the genotoxic potential of this subgroup. The Panel considers the *in vivo* Comet assay as a preferred option to further investigate the genotoxicity *in vivo*. The Comet assay will also be accountable to explore any genotoxicity at the first site of contact where higher concentrations of the test substance are expected to occur. In this view, the *in vivo* Comet assay should be performed on liver, blood and first site of contact (e.g. duodenum or stomach). Alternatively, a transgenic rodent gene mutation assay (OECD TG 488) in tissues including first site of contact would also be acceptable.

Since 2-methylpent-2-enal [FL-no: 05.090] and 2-methylcrotonaldehyde [FL-no: 05.095] are closely related chemical structures, it is expected that they will have a similar reactivity behaviour. Since the evidence for a mutagenic activity *in vitro* is stronger for 2-methylcrotonaldehyde [FL-no: 05.095] than for 2-methylpent-2-enal [FL-no: 05.090], the Panel considers that additional data for the former substance are required. A negative result of 2-methylcrotonaldehyde [FL-no: 05.095] in the *in vivo* assay would be considered representative for the following substances of this subgroup [FL-no: 02.174, 05.033, 05.090, 05.105, 05.107 and 05.126]. A positive result of 2-methylcrotonaldehyde [FL-no: 05.095] in the *in vivo* assay will require further testing of these six substances [FL-no: 02.174, 05.033, 05.090, 05.105, 05.107 and 05.126] in order to finalise their evaluation.

The Panel noted that the Industry has communicated that the following two substances [FL-no: 05.178 and 09.177] are not supported any more. These two substances were selected as representative for the substances in subgroup 1.1.2 and in addition also for substances in subgroup 2.1 (FGE.207). Since no data will be provided for these substances, they cannot further be used as representatives for the substances [FL-no: 02.122, 09.034, 09.712, 09.809] in FGE.207.

2-Methylpent-2-enal [FL-no: 05.090] was originally selected as representative for the subgroup 1.1.2 and also for the substances in subgroup 5.3 (FGE.225). Since the Panel now considers that additional data are required for 2-methylcrotonaldehyde, these data could also be considered representative for the substances in FGE.225 [FL-no: 12.065, 12.079].

The genotoxicity studies are summarised in Appendix D Tables from D.1 to D.6.

2.5.4. Conclusion

Since there is some evidence for 2-methylcrotonaldehyde [FL-no: 05.095] and an indication for 2-methylpent-2-enal [FL-no: 05.090] to show a potency for the induction of gene mutations *in vitro* the Panel considered the mutagenicity hazard not cleared by the endpoints evaluated in the *in vivo* micronucleus assay on 2-methylcrotonaldehyde [FL-no: 05.095]. The Panel therefore concluded that further data are required in order to clarify the genotoxic potential of this subgroup. The Panel considers the *in vivo* Comet assay as a preferred option to further investigate the genotoxicity *in vivo*. Since the evidence for a mutagenic activity *in vitro* is stronger for 2-methylcrotonaldehyde [FL-no: 05.095] than for 2-methylpent-2-enal [FL-no: 05.090], the Panel considers that additional data for 2-methylcrotonaldehyde are required. The Panel concluded that the genotoxicity data for 2-methylcrotonaldehyde cannot be considered representative for the remaining substances of this subgroup [FL-no: 05.130, 05.178, 09.177 and 09.931] for which it was already concluded in the previous version of this FGE that the available data were insufficient to evaluate their genotoxicity.

The Panel noted that this conclusion will also have consequences for the read across for substances in subgroups 2.1 and 5.3 (FGE.207 and FGE.225).

3. Assessment

3.1. Additional data evaluated by the Panel in FGE.201Rev2

New genotoxicity data have been provided for two substances, 2-methylpent-2-enal [FL-no: 05.090] and 2-methylbut-2-enal (2-methylcrotonaldehyde) [FL-no: 05.095]. In Table 2, the newly submitted data are listed and they are summarised in Appendix E, Table E.1.

Table 2: List of genotoxicity studies evaluated in FGE.201Rev2

Substance name	FL-no	<i>In vivo</i> test	Reference
2-Methylpent-2-enal	05.090	Combined MN and Comet assay in liver and duodenum of rats	Keig-Shevlin (2016)
2-Methylcrotonaldehyde	05.095	Comet in liver and duodenum of rats	Bruce (2018)
		Combined gene mutation and micronucleus assay in transgenic rats	JBRC (2014, 2016)

3.1.1. Stability and decomposition products

The Panel noted that in the recently provided *in vivo* genotoxicity study for 2-methylpent-2-enal [FL-no: 05.090], this substance was stored under nitrogen; this, however, does not correspond to the conditions of storage of the flavouring substances expected under normal conditions of use (i.e. storage for 12 months at temperatures < 18°C and out of direct light and air) (EFFA, 2018 in response to EFSA letter dated 9 August 2017, requesting information on storage conditions and chemical stability of [FL-no: 05.090] and requesting to test [FL-no: 05.095] in an *in vivo* comet assay).

To decide whether the substances subjected to genotoxicity testing can be considered representative of the materials of commerce, the Panel requested information on the stability of 2-methylpent-2-enal [FL-no: 05.090] under its intended conditions of use. The applicant provided data on both 2-methylpent-2-enal [FL-no: 05.090] and 2-methylcrotonaldehyde [FL-no: 05.095] from capillary gas chromatographic analyses of freshly prepared flavouring substances and of flavouring substances stored up to the end of their shelf-life or longer.

For 2-methylpent-2-enal [FL-no: 05.090], the purity of fresh samples was 95→ 98% (this purity covers mainly the *E*-isomer that is > 90%). The main secondary component reported was: 2-methyl-2-pentenoic acid (< 0.5% in fresh samples up to 1% in samples after storage) – mainly the (*E*)-2-methyl-2-pentenoic acid was reported. The purity of samples stored up to 4 years (maximum expiration time reported) reported was > 96% (the purity covers mainly the *E*-isomer) and the main secondary components reported were (*E*) and (*Z*)-2-methyl-2-pentenoic acid (up to 1%).

For 2-methylcrotonaldehyde [FL-no: 05.095], the purity of fresh samples was 95→ 98% (this purity covers mainly the *E*-isomer that is > 95%). Secondary components reported were: acetic acid (up to 0.1%), tiglic acid (up to 0.5%) and paraldehyde (up to 1%) (i.e. 2,4,6-trimethyl-1,3,5-trioxane, which is a condensation product – cyclic ether).

The purity of samples stored up to 4 years (maximum expiration time reported) reported was 95–96%. The composition of the secondary components was reported as follows: acetic acid (< 0.5%), tiglic acid (up to 2%) and paraldehyde (up to 2%) (EFFA, 2018).

The Panel concluded that the materials tested in the genotoxicity studies are representative of the material of commerce.

3.1.2. 2-Methylpent-2-enal [FL-no: 05.090] – *in vivo* combined micronucleus and comet assay

The genotoxic potential of 2-methylpent-2-enal [FL-no: 05.090] (purity 99.1%, stored protected from light under nitrogen) was assessed *in vivo* using the bone marrow micronucleus assay combined with the Comet assay in liver and duodenum in the same animals (Keig-Shevlin, 2016). The study was conducted in accordance with GLP, OECD TG 474 (OECD, 2014a) and OECD TG 489 (OECD, 2014b).

In a dose range-finder assay, groups of three male and three female Han Wistar rats were given three administrations (at 0, 24 and 45 h) of 2-methylpent-2-enal, at 1,000, 1,400 or 2,000 mg/kg bw per day. At 1,000 and 1,400 mg/kg bw per day, no clinical signs of toxicity were observed. At 2,000 mg/kg bw per day, clinical signs of toxicity were observed only after the third administration. These included decreased activity, hunched posture, piloerection, lethargy, ataxia and ptosis. One female animal was killed in extremis. All other animals were back to a normal condition by 8 hours post-dose. Minor losses in bodyweight were observed in all three males, but no losses in bodyweight were observed in the two remaining females. Based on this study, a maximum tolerated dose (MTD) of 1,400 mg/kg bw per day was established. As no gender specific effects were seen, only male rats were used in the main study. Groups of six male Han Wistar rats per dose group were administered doses by oral gavage of 0 (corn oil), 350, 700 or 1,400 mg/kg bw of 2-methylpent-2-enal on three consecutive days (0, 24 and 45 h). A satellite group of three male rats were given the same dosing regimen as the 1,400 mg/kg bw per day group rats. A positive control group of three male rats were given doses of 150 mg ethyl methanesulfonate/kg bw at the same time intervals as the dosed groups.

Test animals were examined daily for signs of overt toxicity and body weights were recorded. No changes in body weight, clinical chemistry parameters or histopathology were observed.

Rats were euthanised 3 h after the last dose and 48 h after the initial dose. Blood samples were taken at necropsy for clinical chemistry analysis.

Comet assay

Liver and duodenum cells were prepared for Comet scoring. For both tissue types, the tail moment and tail intensity (%) of a total of 150 cells per animal, split over two to three slides, were recorded.

Both in liver and in duodenum, there was no dose-related increase in %hedgehogs following treatment with 2-methylpent-2-enal demonstrating that treatment did not cause excessive DNA damage that could have interfered with Comet analysis.

In liver, no statistically significant increase in group mean tail intensity and tail moment values was seen in any test substance treatment group compared to the vehicle control treatment group. However, a weak but statistically significant linear trend ($p < 0.05$) was observed. Although the data did not meet the criteria for a clearly negative result, the increases in tail intensity were minor, not statistically significant and fell at the lower end of the historical vehicle control range for tail intensity (0.08–5.08). Therefore, the data were considered to be within the usual variation seen in this assay and of no biological relevance. The positive control provided statistically significant increases in both tail intensity and tail moment.

In duodenum, there were no dose-related increases in the tail intensity or tail moment and no statistically significant results compared to the control group. The positive control provided statistically significant increases in both tail intensity and tail moment.

Micronucleus assay

Bone marrow from the femurs was prepared for micronucleus scoring. A total of at least 500 PCE and normochromatic erythrocytes (NCE) was scored to calculate the degree of bone marrow toxicity by the relative decrease in PCE. For micronuclei (MN) analysis, 4,000 PCE per animal were scored for the presence of MN. In order to improve data interpretation, additional 4,000 PCE were analysed to a total of 8,000 PCE per animal.

2-Methylpent-2-enal [FL-no: 05.090] did not induce micronuclei in bone marrow of rats tested up to 1,400 mg/kg bw per day (MTD). No indication of bone marrow toxicity was observed, because the treatment with 2-methylpent-2-enal [FL-no: 05.090] did not reduce the percentage of PCE. However,

in the range-finding test, at 2,000 mg/kg bw per day (above the MTD), clinical signs of toxicity were observed (including decreased activity, hunched posture, lethargy, ataxia) that could be considered as a line of evidence of systemic exposure.

In the same animals, 2-methylpent-2-enal [FL-no: 05.090] showed negative results in the comet assay both in duodenum and liver. The Panel concluded that 2-methylpent-2-enal [FL-no: 05.090] did not induce DNA damage under the conditions of this study.

3.1.3. 2-Methylcrotonaldehyde [FL-no: 05.095] – *in vivo* combined gene mutation and micronucleus assay in transgenic rats

2-Methylcrotonaldehyde [FL-no: 05.095] (purity 99.5%) was tested in a combined gene mutation and micronucleus assay in transgenic Fisher *gpt* delta rats. Liver and glandular stomach were analysed for gene mutation and peripheral blood erythrocytes for micronuclei (JBRC, 2014 and additional assay 2016). The study was performed in accordance with OECD TG 488 (OECD, 2013) and OECD TG 474 (OECD, 1997).

In a dose range-finding 14-day test, a MTD of 500 mg/kg bw per day was established, based on the observation that one out of three animals died in the 1,000 mg/kg bw per day dose group. In the main study, groups of six transgenic rats were administered 2-methylcrotonaldehyde, by gavage, daily doses of 0, 125, 250 and 500 mg/kg bw per day for 28 days. The solvent, olive oil, was the negative control. As a positive control, one group of six rats was given a single i.p. dose of 125 mg/kg bw of benzo[a]pyrene (B[a]P).

Besides clinical observations of lacrimation and salivation found in some animals in the 250 and 500 mg/kg bw per day groups, no other clear toxicity effects from the test substance were found for body weight, food consumption, gross findings, liver weight, and histopathological lesions of the liver, bone marrow, spleen, stomach, small intestine and large intestine.

Livers from the positive control group were removed 7 days after the treatment. In animals of the other groups, liver and glandular stomach were removed 3 days after the treatment. While liver was analysed immediately for gene mutations (JBRC, 2014), glandular stomach was analysed for gene mutations at a later stage (JBRC, 2016).

For glandular stomach, no positive control was included, but the authors used the results of positive control (B[a]P) in liver. The OECD TG 488 does not provide any suggestion for a positive control to be used in the mutation assay of rat's stomach.

Twenty-four hours after the final dose had been given, blood samples from the tail vein of treated rats were collected for scoring of micronuclei in the immature erythrocytes, and after a manifestation period of 3 days, rats were euthanised.

No historical control data for the performing laboratory were included in the study report but reference was made to published papers.

Gene mutation assay

Genomic DNA was extracted from liver and glandular stomach of treated rats. The isolated *gpt* transgene sequences were packaged into a lambda phage shuttle vector and mutations subsequently detected in *E. coli* YG6020 (6TG selection) and in *E. coli* XL-1Blue MRA (Spi^- selection).

There were no increases in *gpt* and Spi^- mutant frequencies in the liver of the transgenic rats following treatment with 2-methylcrotonaldehyde compared to the negative control whereas significant increases were seen in the positive control, B[a]P (JBRC, 2014).

There were no increases in *gpt* and Spi^- mutant frequencies in the glandular stomach of transgenic rats following treatment with 2-methylcrotonaldehyde compared to the negative control. No positive control was included in the study for the effect in the glandular stomach (JBRC, 2016).

Micronucleus assay

For each slide, 2,000 PCE were scored for MN.

No increases in micronucleated immature erythrocytes in the peripheral blood were observed in the 2-methylcrotonaldehyde treated groups compared to the negative control, while a statistically significant increase was seen in the positive control group.

Based on these results, the authors of the study concluded that 2-methylcrotonaldehyde is not mutagenic in the liver nor in the glandular stomach of *gpt* delta transgenic rats and does not induce micronuclei in the peripheral blood of the same rats.

The Panel noted that there are no indications of bone marrow toxicity because the percentage of PCE is not affected by the treatment with 2-methylcrotonaldehyde. In addition, there are no indications

of bone marrow exposure based on the clinical signs of toxicity observed, therefore the micronucleus assay is inconclusive. Since the potential clastogenicity of [FL-no: 05.095] is not clarified in this study, it was requested to test [FL-no: 05.095] in an *in vivo* comet assay (EFSA letter dated 9 August 2017). The Panel concluded that 2-methylcrotonaldehyde did not induce gene mutations in the liver and the glandular stomach under the conditions applied in this study.

3.1.4. 2-Methylcrotonaldehyde [FL-no: 05.095] - *in vivo* comet assay

2-Methylcrotonaldehyde [FL-no: 05.095] (purity \geq 99%) was tested in a comet assay in liver and duodenum of male Sprague–Dawley rats (Bruce, 2018), in accordance with OECD TG 489 (OECD, 2016) and GLP. Animals were dosed via oral gavage on two consecutive days, the second dose was administered 21 hours after the first dose. The vehicle control used was corn oil and the positive control was ethyl methanesulfonate (EMS). Animals were dosed once with EMS, 3–4 h before euthanasia on day 2.

No dose range-finding experiment was performed. 2-Methylcrotonaldehyde was tested at 250, 500, 1,000 and 2,000 mg/kg bw per day (six animals per group). At the highest dose tested, three animals were found dead. In the surviving animals, reductions in mean group body weights were observed in the 2,000 mg/kg bw per day group.

At 250 and 500 mg/kg bw per day, no clinical signs of toxicity were observed except piloerection at 500 mg/kg bw per day. At 1,000 and 2,000 mg/kg bw per day, clinical signs of toxicity, including piloerection, ataxia, prostration, irregular breathing, hunched position, were observed.

Due to the elevated mortality (3 animals out of six) occurred in the highest treatment group (2,000 mg/kg bw per day) the remaining animals were excluded from the Comet analysis.

For both liver and duodenum, the comet assay resulted in no dose-dependent or statistically significant increases in the % tail DNA in animals dosed with 2-methylcrotonaldehyde up to and including a dose of 1,000 mg/kg bw per day, compared to the concurrent vehicle control group.

In liver and duodenum cells, the positive control, EMS, induced a statistically significant increase in the % tail DNA as compared to the vehicle control groups ($p \leq 0.05$). In the vehicle control group, % tail DNA was within the historical vehicle control range respectively for liver and duodenum.

The authors of the study concluded that under the conditions of this study, 2-methylcrotonaldehyde did not induce DNA damage in liver and duodenum of rats. The Panel agreed with this conclusion.

3.2. Discussion

In FGE.201Rev1, the Panel considered that for 2-methylpent-2-enal [FL-no: 05.090] there was an indication for a weak mutagenic activity in bacteria both in the presence and absence of metabolic activation. *In vitro* assessment of micronucleus induction by 2-methylpent-2-enal [FL-no: 05.090] in the presence and absence of S9 metabolic activation was negative.

In FGE.201Rev1, the Panel considered that for 2-methylcrotonaldehyde [FL-no: 05.095] there is some evidence for a mutagenic activity in bacteria in the presence and absence of metabolic activation. In addition, a dose-dependent induction of structural chromosomal aberrations *in vitro* was observed, both with and without S9-mix. The *in vivo* micronucleus assay on 2-methylcrotonaldehyde [FL-no: 05.095] was not sufficient to overrule the genotoxicity concern; therefore, additional genotoxicity data have been provided that are evaluated in the present revision, FGE.201Rev2.

2-Methylpent-2-enal [FL-no: 05.090] tested in a combined micronucleus and comet assay did not induce DNA damage, overruling the weak gene mutation effect observed in bacteria and confirming the negative results observed in the *in vitro* micronucleus assay.

2-Methylcrotonaldehyde [FL-no: 05.095] did not induce gene mutations *in vivo* in liver and glandular stomach of transgenic rats (gpt and Spi- assay). In addition, 2-methylcrotonaldehyde [FL-no: 05.095] tested in an *in vivo* comet assay in liver and duodenum, it did not induce DNA damage.

The extrapolation from two representative substances to eight candidate substances is intrinsically associated with the introduction of uncertainty. In this opinion, only one toxicological endpoint is addressed (genotoxicity) related to one well defined structural alert, therefore the uncertainty is considered to be limited. Other toxicological endpoints will be addressed in separate opinions.

3.3. Conclusion

Overall, based on the data obtained the Panel concluded that the genotoxic evidence observed *in vitro*, was not confirmed *in vivo*. Since the genotoxicity concern is cleared for the representative substances 2-methylcrotonaldehyde [FL-no: 05.095] and 2-methylpent-2-enal [FL-no: 05.090], all the

ten substances in this subgroup [FL-no: 02.174, 05.033, 05.090, 05.095, 05.105, 05.107, 05.126, 07.261, 12.065 and 12.079] can be evaluated through the Procedure for the evaluation of flavouring substances.

(c): At 1,013.25 hPa, if not otherwise stated.

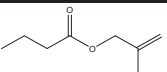

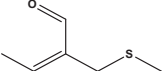

(d): At 20°C, if not otherwise stated.

(e): At 25°C, if not otherwise stated.

Appendix B – Summary of safety evaluation applying the procedure

Table B.1: Summary of safety evaluation of the JECFA substances in the present group (JECFA, 2000, 2004, 2007)

FL-no JECFA-no	EU Register name	Structural formula	EU MSDI ^(a) US MSDI ($\mu\text{g}/\text{capita}$ per day)	Class ^(b) Evaluation procedure path ^(c)	Outcome on the named compound (^(d) or ^(e))	EFSA conclusion on the named compound (genotoxicity)
02.174 1617	2-Methylbut-2-en-1-ol		0.037	Class I A3: Intake below threshold	^(d)	Evaluated in FGE.201Rev2 as of no genotoxicity concern. The substance can be evaluated through the Procedure
05.033 1216	2-Ethylhept-2-enal		0.012 0.1	Class I A3: Intake below threshold	^(d)	Evaluated in FGE.201Rev2 as of no genotoxicity concern. The substance can be evaluated through the Procedure
05.090 1209	2-Methylpent-2-enal		3.4 0.2	Class I A3: Intake below threshold	^(d)	Evaluated in FGE.201Rev2 as of no genotoxicity concern. The substance can be evaluated through the Procedure
05.095 1201	2-Methylcrotonaldehyde		0.61 0.2	Class I A3: Intake below threshold	^(d)	Evaluated in FGE.201Rev2 as of no genotoxicity concern. The substance can be evaluated through the Procedure
05.105 1214	2-Butylbut-2-enal		0.0 0.01	Class I A3: Intake below threshold	^(d)	Evaluated in FGE.201Rev2 as of no genotoxicity concern. The substance can be evaluated through the Procedure
05.107 1215	2-Isopropyl-5-methylhex-2-enal		0.24 0.01	Class I A3: Intake below threshold	^(d)	Evaluated in FGE.201Rev2 as of no genotoxicity concern. The substance can be evaluated through the Procedure
05.126 1217	2-Methyloct-2-enal		0.0 7.9	Class I A3: Intake below threshold	^(d)	Evaluated in FGE.201Rev2 as of no genotoxicity concern. The substance can be evaluated through the Procedure
05.130	alpha-Sinensal			Not evaluated by JECFA		Substance not in the Register
05.178 1227	beta-Sinensal		0.91 0.5	Class I A3: Intake below threshold	^(d)	Substance not supported by industry
07.261	4-Methyl-3-hepten-5-one		–	Not evaluated by JECFA		Evaluated in FGE.201Rev2 as of no genotoxicity concern. The substance can be evaluated through the Procedure

FL-no JECFA-no	EU Register name	Structural formula	EU MSDI ^(a) US MSDI ($\mu\text{g}/\text{capita}$ per day)	Class ^(b) Evaluation procedure path ^(c)	Outcome on the named compound (^(d) or ^(e))	EFSA conclusion on the named compound (genotoxicity)
09.177 1207	2-Methylallyl butyrate		ND 0.2	Class I A3: Intake below threshold	^(d)	Substance not supported by industry
09.931 1226	2,6-Dimethyl-2,5,7- octariene-1-ol acetate		1.2 7.7	Class I A3: Intake below threshold	^(d)	Evaluated in FGE.207, as of no genotoxicity concern and evaluated through the Procedure in FGE.72Rev1
12.065 471	2,8-Dithianon-4-en-4- carboxaldehyde		0.012 0.1	Class I JECFA evaluated at step B5: intake below 1.5 $\mu\text{g}/\text{person}$ per day	^(d)	Evaluated in FGE.201Rev2 as of no genotoxicity concern. The substance can be evaluated through the Procedure
12.079 470	2-(Methylthiomethyl) but-2-enal		0.024 0.1	Class I JECFA evaluated at step B5: intake below 1.5 $\mu\text{g}/\text{person}$ per day	^(d)	Evaluated in FGE.201Rev2 as of no genotoxicity concern. The substance can be evaluated through the Procedure

ND: not determined; JECFA: The Joint FAO/WHO Expert Committee on Food Additives; FL-no: FLAVIS number; MSDI: maximised survey-derived daily intake; FGE: Flavouring Group Evaluation.

(a): EU MSDI: Amount added to food as flavour in (kg/year) $\times 10^9 / (0.1 \times \text{population in Europe} (= 375 \times 10^6) \times 0.6 \times 365) = \mu\text{g}/\text{capita}$ per day.

(b): Thresholds of concern: Class I = 1,800 $\mu\text{g}/\text{person}/\text{day}$, Class II = 540 $\mu\text{g}/\text{person}/\text{day}$, Class III = 90 $\mu\text{g}/\text{person}$ per day.

(c): Procedure path A substances can be predicted to be metabolised to innocuous products. Procedure path B substances cannot.

(d): No safety concern based on intake calculated by the MSDI approach of the named compound.

(e): Data must be available on the substance or closely related substances to perform a safety evaluation.

Appendix C – (Q)SAR predictions

Table C.1: (Q)SAR predictions on mutagenicity for aldehydes representing the substances in subgroup 1.1.2

(f): MultiCase Chromosomal aberration in CHL (OD: Out of domain; POS: Positive; NEG: Negative; EQU: Equivocal).

OD, out of applicability domain: not matching the range of conditions where a reliable prediction can be obtained in this model. These conditions may be physicochemical, structural, biological, etc.

Appendix D – Genotoxicity data evaluated in FGE.201Rev1

In vitro studies available for the group of aldehydes and the aldehydes anticipated to be formed from the precursors in subgroup 1.1.2.

Table D.1: Genotoxicity studies *in vitro*

Chemical Name [FL-no]	Test system	Test object	Concentration	Reported Result	Reference	Comments ^(b)
2-Methylpent-2-enal [05.090]	Reverse mutation	<i>Salmonella</i> Typhimurium TA98, TA100	0.03–3 mmol/plate (2.94–294 mg/plate)	Negative ^(a)	Florin et al. (1980)	Insufficient validity (spot test, not according to OECD guideline, methods and results insufficiently reported)
		<i>S. Typhimurium</i> TA98, TA100, TA102, TA1535 and TA1537	1.6, 8, 40, 200, 1,000 and 5,000 µg/plate	Negative ^{(a),(c)}	Bowen (2011)	^(d) Valid. The study was performed in compliance with GLP and according to OECD TG 471
			78.13, 156.13, 312.5, 625, 1,250, 2,500 and 5,000 µg/plate	Negative ^{(a),(h)}		
		<i>S. Typhimurium</i> TA100	1.6, 8, 40, 200, 1,000 and 5,000 µg/plate	Negative (–S9, Plate) ^{(a),(c)} Weakly positive (+S9, Plate)	Ballantyne (2011)	^(g) Valid. The study was performed in compliance with GLP and according to OECD TG 471 except that only one bacterial strain was used
			51.2, 128, 320, 800, 2,000 and 5,000 µg/plate	Weakly positive (–S9, Plate) ^{(c),(e)}		
			8.192, 20.48, 51.2, 128, 320, 800, 2,000 and 5,000 µg/plate	Weakly positive (+S9, Plate) Negative (+S9, Pre-inc) ^{(c),(h),(i)}		
	51.2, 128, 320, 800, 2,000 and 5,000 µg/plate		Weakly positive (–S9, Plate) ^{(c),(e)}			
	Micronucleus induction	Human peripheral blood lymphocytes	100, 200 and 300 µg/ml	Negative ^{(e),(j)}	Whitwell (2011)	^(k) Valid. The study was performed in compliance with GLP and according to OECD TG 487
			200, 275 and 350 µg/ml	Negative ^{(i),(j)}		
			20, 50, 70 and 80 µg/ml 100, 175, 260 and 300	Negative ^{(e),(l)} Negative ^{(c),(j)}		

Chemical Name [FL-no]	Test system	Test object	Concentration	Reported Result	Reference	Comments ^(b)
2-methylacrolein 2-Methyl-2-propenal	Ames test	<i>S. Typhimurium</i> TA100	0–2 µmol/plate (–S9) 0–9 µmol/plate (+S9)	Positive ^(a)	Eder and Deininger (2001)	Valid. Positive both with and without S9-mix. Toxic at 1 µmol/plate and above (–S9) and 6 µmol/plate (+S9) evident as a reduction in revertants
2-Methylcrotonaldehyde [05.095]	Reverse mutation	<i>S. Typhimurium</i> TA98, TA100, TA1535, TA1537, and <i>Escherichia coli</i> WP2uvrA	8.19, 20.5, 51.2, 128, 320, 800, 2,000 and 5,000 µg/plate	Positive ^{(a),(c)} (TA100)	Nakajima (2006a)	^(m) Valid. According to the study report, the study was performed in compliance with Japanese GLP standards. The study report contained a certificate of reliability but no details of inspection. The study is in accordance with OECD except that only two plates were used per concentration. No statistics performed.
			156, 313, 625, 1,250, 2,500 and 5000 µg/plate	Positive ^{(a),(c)} (TA100) Weakly positive (WP2uvrA, –S9)		
		<i>E. coli</i> WP2uvrA	156, 313, 625, 1,250, 2,500 and 5,000 µg/plate	Negative ^(a)		
			<i>S. Typhimurium</i> TA100	1.6, 8, 40, 200, 1,000 and 5,000 µg/plate		
	51.2, 128, 320, 800, 2,000 and 5,000 µg/ plate	Weakly positive (+/–S9, Plate) ^{(a),(c)}				
8.192, 20.48, 51.2, 128, 320, 800, 2,000 and 5,000 µg/plate	Weakly positive (+S9, Pre) ^{(h),(i)}					
0.32, 1.6, 8, 40, 200, 1,000 and 5,000 µg/ plate	Weakly positive (+S9, Plate) ^{(c),(i)}					
Chromosomal aberration	Chinese hamster Pulmonic fibroblasts	105, 210 and 421 µg/mL without S-9 treatment and 105, 210, 421 and 841 µg/mL with S-9 treatment	Positive	Nakajima (2006b)	^(o) Valid. According to the study report, the study was performed in compliance with Japanese GLP standards. The study report contained a certificate of reliability but no details of inspection. Mainly in accordance with OECD TG 473	

- (a): With and without metabolic activation.
- (b): Validity of genotoxicity studies:
Valid.
Limited validity (e.g. if certain aspects are not in accordance with OECD guidelines or current standards and/or limited documentation).
Insufficient validity (e.g. if main aspects are not in accordance with any recognised guidelines (e.g. OECD) or current standards inappropriate/not validated test system).
Validity cannot be evaluated (e.g. insufficient documentation, short abstract only, too little experimental details provided, text not in a Community language).
- (c): Plate incorporation method.
- (d): Toxicity was observed in TA1537 at 5,000 µg/plate in the presence of S-9 and in TA102 at 1,000 µg/plate and above in the presence of S-9.
- (e): Without S9 metabolic activation.
- (f): Toxicity was observed in all strains in the presence of S-9 above 2,500 µg/plate and 1,250 µg/plate in TA1537. Study design complied with current recommendations. Acceptable top concentrations were achieved.
- (g): Throughout experiments some small but statistically significant increases were seen but these were attributed to normal biological variability, and were generally less than 2-fold over concurrent vehicle controls.
- (h): Pre-incubation method.
- (i): With S9 metabolic activation.
- (j): 3-hours incubation with 21-hours recovery period.
- (k): Complies with draft OECD guideline 487. Acceptable levels of cytotoxicity were achieved at the top concentrations used in all parts of the study.
- (l): 24-hours incubation with no recovery period.
- (m): Study design complied with current recommendations. Acceptable top concentrations were achieved.
- (n): Throughout experiments some small but statistically significant increases were generally less than 2-fold over concurrent vehicle controls.
- (o): Dose-dependent increase in induction of structural chromosomal aberrations with and without S-9 treatment. No changes in numerical chromosomal aberrations were observed.

One *in vivo* study is available for the group of aldehydes and the aldehydes anticipated to be formed from the precursors in subgroup 1.1.2.

Table D.2: Genotoxicity studies *in vivo* evaluated in FGE.201Rev1

Chemical Name [FL-no]	Test system	Test object	Dose	Reported Result	Reference	Comments ^(a)
<i>Trans</i> -2-methyl-2-butenal[05.095]	<i>In vivo</i> micronucleus induction	BDF ₁ male mice	250, 500 and 1,000 mg/kg bw per day by oral gavage	Negative	Nakajima (2007)	Valid. According to the study report, the study was performed in compliance with Japanese GLP standards. The study report contained a certificate of reliability but no details of inspection. The Panel considered the study to be compliant with OECD guideline 474 except that no justification for the use of a single sex was given in the report, i.e. no data demonstrating that there are no substantial differences between sexes in toxicity

bw: body weight; GLP: Good Laboratory Practice.

- (a): Validity of the genotoxicity studies:
Valid.
Limited validity (e.g. if certain aspects are not in accordance with OECD guidelines or current standards and/or limited documentation).
Insufficient validity (e.g. if main aspects are not in accordance with any recognised guidelines (e.g. OECD) or current standards inappropriate/not validated test system).
Validity cannot be evaluated (e.g. insufficient documentation, short abstract only, too little experimental details provided, text not in a Community language).

Table D.3: Ames test with 2-methyl-2-butenal [05.095] (Nakajima, 2006a) Non-toxic effects

	S9	Assay	TA98	TA100	TA1535	TA1537	WP2uvrA	Comment	Conclusion
Range-finding experiment	–	Pre	1.4-fold < HC d-r	3-fold > HC d-r	2.0-fold < HC not d-r	1.6-fold < HC not d-r	1.2-fold < HC (d-r)		Positive in TA 100
	+	Pre	1.2-fold < HC (d-r)	3.9-fold > HC d-r	1.4-fold < HC not d-r	1.0-fold < HC	1.3-fold < HC (d-r)		Positive in TA 100
Experiment 1	–	Pre	2.0-fold > HC not d-r	7.2-fold > HC d-r	1.8-fold < HC not d-r	1.9-fold < HC (d-r)	2.1-fold > HC (d-r)	WP2uvrA-result not clearly reproducible	Positive in TA 100, equivocal in WP2uvrA
	+	Pre	1.5-fold < HC (d-r)	4.6-fold > HC d-r	1.5-fold < HC not d-r	1.0-fold < HC	1.2-fold < HC not d-r		Positive in TA 100
Experiment 2	–	Pre					1.4-fold > HC (d-r)		Equivocal
	+	Pre							

Two plates were used per concentration. No examinations using statistical procedures were conducted.

> HC: above historical control; < HC: within historical control.

d-r: dose-related; (d-r), not clearly dose-related but the highest dose resulted in the largest increase, not d-r, not dose-related.

Pre: Pre-incubation assay.

Table D.4: Ames test with 2-methylpent-2-enal [05.090] (Bowen, 2011) Statistically significant increases, non-toxic effects

	S9	Assay	TA98	TA100	TA1535	TA1537	TA102	Conclusion
Range-finding experiment	–	Plate		1.2-fold < HC d-r				Negative
	+	Plate		1.2-fold < HC not d-r				Negative
Experiment 1	–	Plate	NS	NS	NS	NS	NS	Negative

Table E.1: Summary of additional genotoxicity data submitted for FGE.201Rev2 *in vivo*

FL-no	Chemical name	Test system <i>in vivo</i>	Test object route	Concentrations of substance mg/kg bw per day	Result	Reference	Comments
05.090	2-Methylpent-2-enal	Comet (liver and duodenum)	Han Wistar rats Oral gavage	0 (corn oil), 350, 700 and 1,400	Negative	Keig-Shevlin (2016)	Study performed in accordance with OECD TG 489
		Micronucleus (bone marrow)			Negative		Study performed in accordance with OECD TG 474
05.095	2-Methylbut-2-enal	Micronucleus (peripheral blood erythrocytes)	Fisher gpt delta rats Oral gavage	0 (olive oil), 125, 250 and 500	Negative	JBRC (2014)	The study was performed in 2014 and analysed in two different phases (2014 and 2016). Study performed in accordance with OECD TG 488 and OECD TG474
		Gene Mutation assay gpt/Spi ⁻ (liver)			Negative		
		Gene Mutation assay gpt/Spi ⁻ (stomach)			Negative	JBRC (2014, 2016)	
		Comet (liver and duodenum)	Sprague-Dawley rats Oral gavage	0 (corn oil), 250, 500, 1,000 and 2,000	Negative	Bruce (2018)
