# The gonadal effects of diabetes

Ethel Codner

From 7th APPES Biennial Scientific Meeting  
Nusa Dua, Bali. 14-17 November 2012

The functional reproductive alterations seen in women with type 1 diabetes (T1D) have changed as therapy has improved. Historically, patients with T1D and insufficient metabolic control exhibited a high prevalence of amenorrhea, hypogonadism, and infertility. Recent publications have shown that in spite of intensive insulin therapy, some delay in the age of thelarche, pubarche and menarche is still observed in girls with T1D. In addition, ovarian hyperandrogenism may be observed during late adolescence and an increased prevalence of hirsutism and polycystic ovarian syndrome (PCOS) has been described in adult women with T1D. These endocrine abnormalities may be related to non-physiologic insulin replacement therapy and to hyperglycemia.

Insulin is well known for its effects on carbohydrate metabolism, but this hormone also plays an important role in regulating ovarian function. Granulosa, theca and stromal ovarian cells may be affected by insulin deficiency or excess, which may be present in women with type 1 diabetes mellitus (T1D)[1]. Diabetes disrupts hypothalamic-pituitary-ovarian function, as documented by animal model studies which have helped to decipher the underlying basis of these conditions and have highlighted the variable contributions of defective leptin, insulin and kisspeptin signalling to the mechanisms of perturbed reproduction in T1D[2].

Effects of diabetes on gonadal function vary according to the age of the patient. Young girls during adrenarche exhibit an elevation of DHEAS, androstenedione, inhibin B and anti-müllerian hormone[3], an endocrine profile that is similar to the one observed in young girls at risk of developing polycystic ovarian syndrome later in life. During puberty a delay in pubertal development has been described which is followed by menstrual irregularities and hyperandrogenism during adolescence [1,4,5]. Despite these abnormalities in ovarian function, ovulatory functions are preserved in adolescents with type 1

diabetes[6]. Later in life, adult women with type 1 diabetes exhibit PCOS, polycystic ovaries at the ultrasonographic exam, menstrual irregularities and early decline in ovarian reserve[7-9].

Clearly, despite improvements in insulin therapy, T1D patients still suffer several significant clinical problems, such as pubertal delay, menstrual disturbances and hyperandrogenism which may ultimately lead to the development of PCOS in adulthood. (Fondacyt 1100123 y 1050452)
