Background: There is a need for a survey instrument to measure arthralgia (joint pain) that has been psychometrically validated in the context of existing reference instruments. We developed the 16-item Patient-Reported Arthralgia Inventory (PRAI) to measure arthralgia severity in 16 joints, in the context of a longitudinal cohort study to assess aromatase inhibitor-associated arthralgia in breast cancer survivors and arthralgia in postmenopausal women without breast cancer. We sought to evaluate the reliability and validity of the PRAI instrument in these populations, as well as to examine the relationship of patient-reported morning stiffness and arthralgia.

Methods: We administered the PRAI on paper in 294 women (94 initiating aromatase inhibitor therapy and 200 postmenopausal women without breast cancer) at weeks 0, 2, 4, 6, 8, 12, 16, and 52, as well as once in 36 women who had taken but were no longer taking aromatase inhibitor therapy.

Results: Cronbach's alpha was 0.9 for internal consistency of the PRAI. Intraclass correlation coefficients of test-retest reliability were in the range of 0.87–0.96 over repeated PRAI administrations; arthralgia severity was higher in the non-cancer group at baseline than at subsequent assessments. Women with joint comorbidities tended to have higher PRAI scores than those without (estimated difference in mean scores: -0.3 , 95% confidence interval [CI] -0.5 , -0.2 ; $P < 0.001$). The PRAI was highly correlated with the Functional Assessment of Cancer Therapy-Endocrine Subscale item "I have pain in my joints" (reference instrument; Spearman r range: 0.76–0.82). Greater arthralgia severity on the PRAI was also related to decreased physical function ($r = -0.47$, 95% CI -0.55 , -0.37 ; $P < 0.001$), higher pain interference ($r = 0.65$, 95% CI 0.57–0.72; $P < 0.001$), less active performance status (estimated difference in location -0.6 , 95% CI -0.9 , -0.4 ; $P < 0.001$), and increased morning stiffness duration ($r = 0.62$, 95% CI 0.54–0.69; $P < 0.0001$).

Conclusion: We conclude that the psychometric properties of the PRAI are satisfactory for measuring arthralgia severity.

Keywords: arthralgia, joint pain, pain measurement, validation studies, questionnaire design, aromatase inhibitors, postmenopause

Introduction

The Menopause Quality of Life/Breast Cancer Adjuvant Therapy longitudinal cohort study was initiated in 2009 to investigate arthralgia (defined as inflammatory or non-inflammatory joint pain) in postmenopausal women without breast cancer and in women undergoing aromatase inhibitor (AI) therapy. Since 2006, AIs have been the standard of care to prevent recurrence of hormone-sensitive early breast cancer in postmenopausal women. Arthralgia occurs more frequently with age,^{1,2} and is a noted secondary effect of AIs.^{3–6}

While several validated instruments exist to measure arthritis (inflammatory joint pain),^{7–15} options for measuring arthralgia are limited. Because it may be non-inflammatory, arthralgia might not manifest signs that are readily measurable by a clinician. Hence, finding external and objective clinical criteria to measure arthralgia effectively poses even more of a challenge than it does for arthritis. Clinical arthritis assessments such as the Disease Activity Index for Rheumatoid Arthritis¹⁶ are made up of subscales of tender and swollen joint counts. Among rheumatoid arthritis patients, Pearson correlation coefficients for clinician–patient agreement on tender and swollen joint counts have been estimated in meta-analysis to be 0.61 (tender) and 0.44 (swollen).¹⁷ Thus, even with inflammatory joint pain, which has an externally observable component, patients' self-assessments are often quite different from clinicians' evaluations.

Magnetic resonance imaging may reveal disease processes of AI-associated arthralgia.^{18–20} However, as is often the case with the measurement of pain, no simple low-cost clinical test or biomarker for arthralgia is available for use in regular clinical practice. In addition, the role of inflammation and other biomarkers in arthralgia remains unclear; past efforts have been unsuccessful in validating patient-reported arthritis pain instruments against erythrocyte sedimentation rate, C-reactive protein, antinuclear antibodies, anti-double-stranded DNA, anticyclic citrullinated peptide, rheumatoid factor, and uric acid.^{21,22} Therefore, the vast majority of research and clinical practice must rely on patient reports for assessment of arthralgia.

The Western Ontario and McMaster Universities Arthritis Index⁷ and Joint-Specific Multidimensional Assessment of Pain²³ measure pain intensity and affect, but in only one joint at a time (eg, knees). The Joint-Specific Multidimensional Assessment of Pain includes ten items per joint queried. These scales do not allow one to study arthralgia in multiple joints simultaneously, yet arthralgia was observed to occur in more than one joint location in the Breast Cancer Adjuvant Therapy cohort study.⁵ Querying only one specific joint or bilateral joint pair could miss potential statistically or clinically significant arthralgia in other areas of the body. The Regional Pain Scale comes closer to measuring the construct of pain throughout the body, but queries pain severity in both nonarticular and articular regions. The Regional Pain Scale has only four response options (none, mild, moderate, or severe),²⁴ while 11-point (0–10) numeric rating scales have been demonstrated in past methodological research to have a higher degree of sensitivity and validity for pain assessment.²⁵

A reliable and valid measure of arthralgia severity is needed to assemble consistent epidemiological outcomes information about prevalence, incidence, time to onset, risk factors, severity, and duration of arthralgia, as well as to better understand the role of arthralgia in the effectiveness of AI treatment and the relationship between inflammation and AI-associated arthralgia. Such a measure is also needed to develop AI adherence interventions based on arthralgia management strategies; improving management of arthralgia has been suggested as the key to promoting AI adherence.²⁶

In order to address the need for a valid and reliable arthralgia severity measurement instrument, we developed the Patient-Reported Arthralgia Inventory (PRAI) in the context of a longitudinal cohort study of arthralgia, health-related quality of life, and medication adherence. We adapted the PRAI from the articular regions of the Regional Pain Scale in collaboration with its author,²⁴ revising the response options to follow best practices in patient-reported outcome measurement²⁷ and pain measurement. The PRAI uses a 0–10 numeric rating scale to assess pain severity over a recall period of the preceding 7 days. Our objectives were to evaluate the psychometric properties of the PRAI, assessing the scale's reliability and construct validity, and exploring how duration of morning stiffness relates to arthralgia.

Materials and methods

Study design and setting

Survey data were collected in a longitudinal prospective cohort study (ClinicalTrials.gov identifier NCT00954564), with 52 weeks of follow-up per participant. Written informed consent was obtained from each study participant. The study was approved by the Vanderbilt University institutional review board and consisted of self-administered paper questionnaires completed at weeks 0, 2, 4, 6, 8, 12, and 52. Study personnel at Vanderbilt Ingram Cancer Center, Vanderbilt Institute for Medicine and Public Health, and Vanderbilt Women's Health Research conducted the screening, enrollment, data collection, and analysis. Data were managed using Research Electronic Data Capture (REDCap).²⁸

Participants

We recruited participants into three groups: women initiating AIs, women who had taken AIs but were no longer on AI therapy, and postmenopausal women who had never been diagnosed with breast cancer (comparison group). We chose these three groups to serve the aims of our parent study's program of research to understand the time course and duration of treatment-emergent arthralgia with regard to AI initiation and

cessation. Because arthralgia is common in postmenopausal women irrespective of breast cancer diagnosis or endocrine therapy (affecting 45%–55% of the population),^{1,2} the comparison group was selected to assess the background rate of arthralgia in menopause, thus helping us quantify treatment-emergent arthralgia severity in the parent study. Participants were recruited either by their treating physician at the Vanderbilt University Medical Center or via study advertisements in the greater Nashville area between 2009 and 2013. Participants in all groups had to be female, postmenopausal (self-report of at least 12 months without a menstrual period, unrelated to surgery or medication), 35–90 years of age, and have active self-reported performance status (≤ 3).²⁹

Participants in the first group had to initiate anastrozole, exemestane, or letrozole within 30 days of baseline assessment. Those in the second group had to have taken one of these three medications in the past and since discontinued for any reason. Comparison group participants had to acknowledge never having been told by a physician that they had breast cancer. Patients were ineligible if they were undergoing treatment for any other (nonbreast) cancer, were unable to provide informed consent, did not speak English, were pregnant, or had metastatic disease. Screening was done by telephone or via online self-administration. For the group of women who had stopped taking AIs, only a baseline survey was administered. Follow-up for the longitudinal AI and comparison groups was done by telephone and mail contact to assist participants in staying on schedule. Women were considered lost to follow-up if they had missed more than two surveys in a row and could not be reached after six attempts. Cohort screening and enrollment, as well as the derivation of the final analytic sample, are shown in Figure 1.

Variables

We developed and administered the PRAI for the purpose of measuring arthralgia severity in multiple joint locations. The PRAI consists of 16 items that query pain severity over the last 7 days in eight joint pair groups: bilateral (left and right as two separate sets of items) fingers, wrists, elbows, shoulders, hips, knees, ankles, and toes. The questionnaire uses a rating scale of 0–10, with 10 being greatest severity (Table S1). We scored the PRAI by first calculating the sum of responses across all joints, ranging from 0 to 160. For ease of interpretation, the average severity of pain per joint (0–10) was then calculated by dividing the total score by the number of items answered.

Data on several related constructs were collected concomitantly with the PRAI. Comorbidities were assessed using

a checklist. For the analyses we categorized comorbidities as joint-related (osteoarthritis, rheumatoid arthritis, psoriatic arthritis, lupus, gout, ankylosing spondylitis, fibromyalgia, osteoporosis, osteopenia, or Sjogren's syndrome) or not joint-related (diabetes, heart disease, hypertension, chronic obstructive pulmonary disease, Parkinson's disease, renal failure, urinary tract problems, gastrointestinal problems, anemia, eye problems, or no other comorbidity). We assessed physical function and pain interference using the previously validated Patient-Reported Measurement Information System (PROMIS) scales.^{30,31} PROMIS physical function and pain interference scores were standardized according to the PROMIS instructions. We measured performance status using a patient-reported adaptation of the Eastern Cooperative Oncology Group (ECOG) performance status measure.³² The Functional Assessment of Cancer Therapy-Endocrine Subscale (FACT-ES) was administered to measure menopausal symptom severity.³³ The last item of the FACT-ES instrument is "I have pain in my joints", with the following response options: "None," "A little bit," "Somewhat," "Quite a bit," and "Very much." This item about arthralgia was added to the FACT-ES as a result of the findings regarding secondary effects of the AI anastrozole in the Arimidex, Tamoxifen Alone or in Combination trial.^{34,35}

As a patient-reported proxy for the presence of inflammation,³⁶ we collected information regarding the duration of morning stiffness in minutes. Respondents who answered "yes" to the question "Over the past 7 days, have you had overall morning stiffness in your muscles or joints?" were asked how many minutes the morning stiffness had lasted. A check box was available to indicate if the morning stiffness had lasted more than 120 minutes. If a value for duration was entered and the "more than 120 minutes" box checked, we used the reported value.

Statistical methods

To assess the reliability of the PRAI, we calculated its internal consistency via Cronbach's alpha for the overall score and for the score with each item removed. Additionally, we assessed test-retest reliability in the comparison group, in which minimal change would be expected, by examining the change in scores assessed at 2-week intervals (weeks 0 and 2, weeks 2 and 4, and so on). For each set of biweekly measurements, we computed a Spearman correlation coefficient with a 95% confidence interval (CI) to assess the strength of associations, and generated Bland-Altman plots to evaluate agreement. We also computed the intraclass correlation coefficient (ICC) and corresponding CIs.

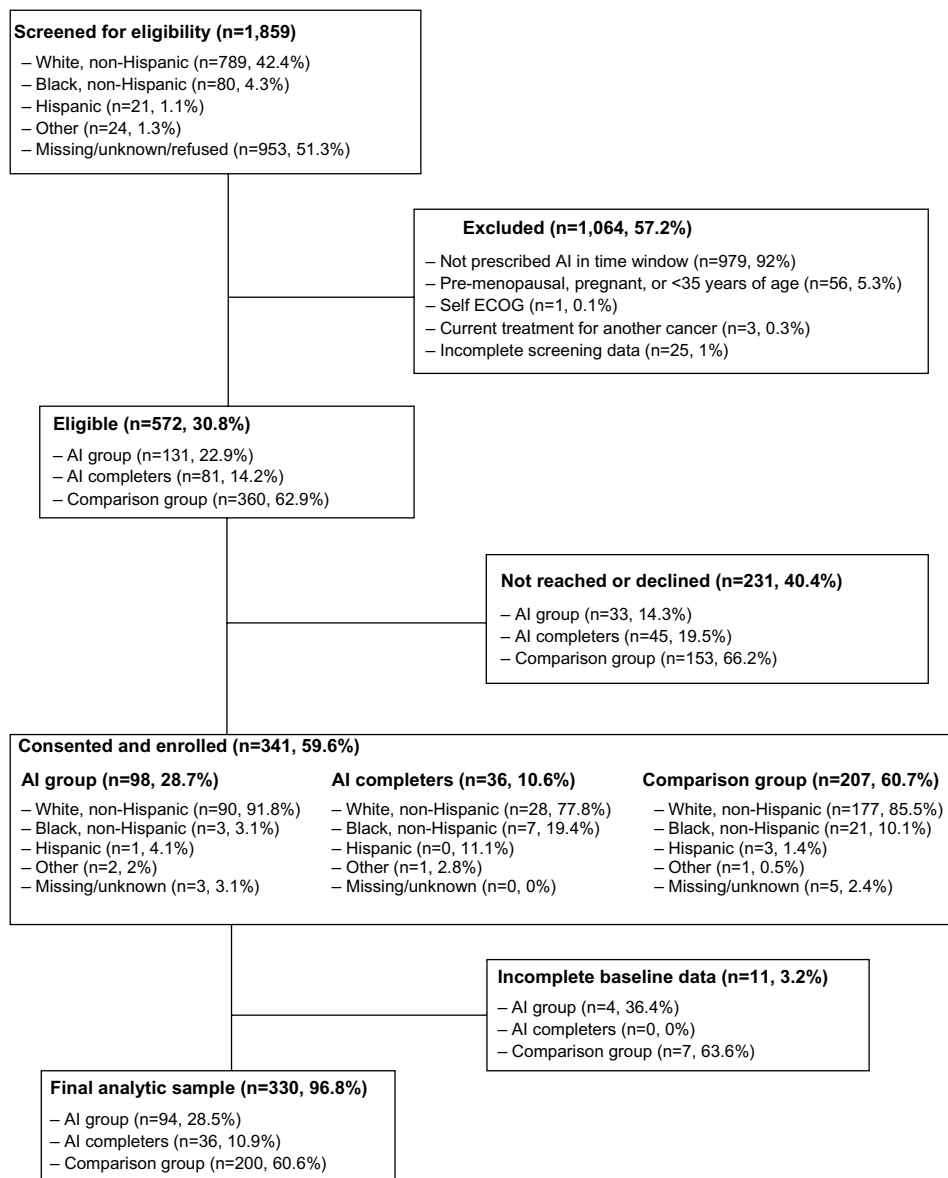

Figure 1 Flow diagram of cohort screening and enrollment.
Abbreviations: AI, aromatase inhibitor; ECOG, Eastern Cooperative Oncology Group.

To examine the construct validity of the PRAI, we assessed both known-groups validity and convergent validity. Known-groups validity was addressed by: comparing PRAI scores of AI patients with those of comparison group subjects at baseline and over time; and comparing PRAI scores of patients with joint comorbidities with those without joint comorbidities at baseline. Wilcoxon rank-sum tests and boxplots were used to assess differences in groups for each of the above comparisons. We assessed concurrent validity by comparing PRAI scores at baseline and at follow-up with scores from the single FACT-ES question reporting pain in joints. To assess convergent validity, we examined whether PRAI scores correlated with other validated measures, including the

PROMIS physical function, PROMIS pain interference, and ECOG performance status. Spearman correlation coefficients and CIs were used to evaluate these associations.

To better understand the relationship between morning stiffness and arthralgia, we examined the association of PRAI scores with patient-reported duration of morning stiffness using Spearman correlation coefficients, Bland-Altman plots, and ICCs. CIs for Spearman correlation coefficients were obtained using percentiles of bootstrap samples.

Results

Data from 330 women were included in the final analysis (Figure 1). A detailed breakdown of population characteristics,

Table 1 Estimated ICC and Spearman ρ for PRAI scores for one patient taken 2 weeks apart

Weeks	Test	Test statistic	95% CI	P-value
0, 2	ICC	0.87	0.82–0.90	<0.0001
2, 4		0.94	0.92–0.96	<0.0001
4, 6		0.94	0.91–0.95	<0.0001
6, 8		0.96	0.94–0.97	<0.0001
0, 2	Spearman ρ	0.71	0.59–0.80	<0.0001
2, 4		0.86	0.78–0.91	<0.0001
4, 6		0.85	0.77–0.91	<0.0001
6, 8		0.84	0.76–0.90	<0.0001

Abbreviations: CI, confidence interval ; PRAI, Patient-Reported Arthralgia Inventory; ICC, intraclass coefficient.

univariate descriptive characteristics, and univariate comparisons by group can be found in Castel et al.⁵ The individual PRAI items were all highly positively skewed; the median value for all items was zero. Respondents reported the lowest arthralgia severity in the elbows and higher arthralgia severity in the knees, hips, and shoulders. Cronbach's alpha for the PRAI pain severity items was estimated to be 0.90. None of the alpha values based on individual item removal were greater than the total alpha, indicating that no item was negatively affecting the scale's internal consistency reliability.

Test-retest reliability is reported in the form of ICC coefficients, which were calculated within subjects in

the comparison group using PRAI assessments collected 2 weeks apart (Table 1). ICC values ranged from 0.87 to 0.96 for the repeated assessments. The corresponding Spearman correlation coefficient estimates also indicate fairly strong associations (range: 0.71–0.86). The Bland-Altman plots in Figure 2 show levels of agreement between assessments taken 2 weeks apart. There is strong overall agreement, with less agreement between weeks 0 and 2 than at subsequent time points.

With regard to validity, Figure 3 shows boxplots of baseline PRAI scores for those participants with and without joint comorbidities. The estimated difference in mean scores between groups was -0.3 (CI $-0.5, -0.2$; $P < 0.001$). As expected, women with joint comorbidities tended to have higher arthralgia severity scores than those without joint comorbidities. The Wilcoxon rank-sum test of the null hypothesis that both groups had the same distribution of scores was highly significant ($P < 0.001$), suggesting known-groups validity with respect to joint comorbidity.

Figure 4 shows boxplots of the PRAI scores in relation to different levels of response to the FACT-ES item "I have pain in my joints" separately by week. The PRAI scores increase with higher FACT-ES ratings, further indicating known-groups validity. Table 2 lists the Spearman correlation estimates between the two measures over time, which

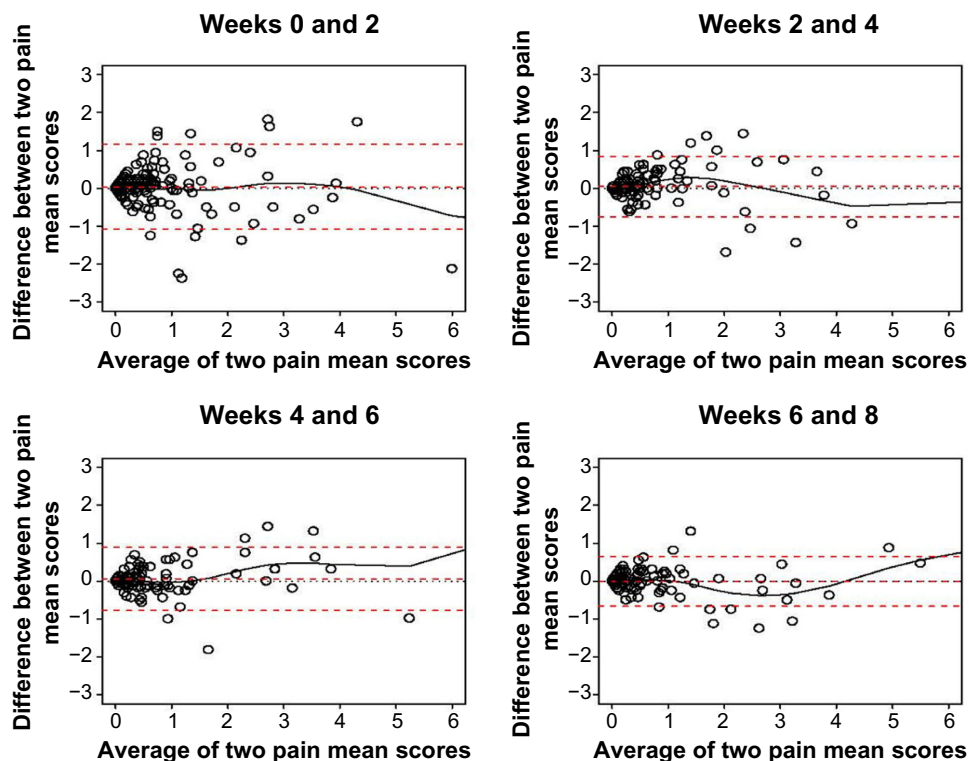

Figure 2 Test-retest reliability. Bland-Altman plot of agreement between Patient-Reported Arthralgia Inventory assessments taken 2 weeks apart, with smoothed curve.

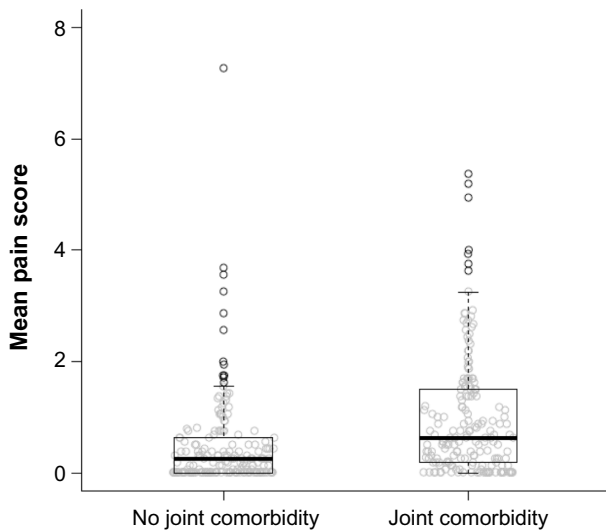

Figure 3 Baseline mean Patient-Reported Arthralgia Inventory scores by presence of joint comorbidity.

show high associations (range: 0.76–0.82). This supports the concurrent validity of the PRAI.

We assessed convergent validity by examining the relationship between the mean PRAI scores and each of the PROMIS physical function T scores, PROMIS pain interference T scores, and ECOG performance status. PRAI scores tended to be lower among those with better physical function scores (estimated Spearman correlation coefficient: -0.47 , 95% CI $-0.55, -0.37$; $P < 0.001$). PRAI scores were higher among those with higher PROMIS pain interference (estimated Spearman correlation coefficient: 0.65 , 95% CI

$0.57-0.72$; $P < 0.001$). ECOG performance status that was not fully active was associated with higher PRAI scores (estimated difference in location scores: -0.6 , 95% CI $-0.9, -0.4$; $P < 0.001$).

Figure 5 shows a plot of the duration of morning stiffness in minutes and PRAI scores at baseline. The Spearman correlation between these measures was 0.62 (95% CI $0.54-0.69$; $P < 0.0001$), indicating greater morning stiffness among those women with higher PRAI scores.

Discussion

Since the discovery of arthralgia as a secondary effect of AIs, there has been a need for a validated multi-item arthralgia measurement instrument. Our overall objective was to understand the psychometric properties of the PRAI. Our findings can be interpreted in the context of established thresholds for strength of association. For Cronbach’s alpha,³⁷ a threshold value of 0.70 indicates good internal consistency;³⁸ we observed very high internal consistency reliability (0.90) among the PRAI pain severity items. Similarly, 0.70 is a criterion for adequate test-retest reliability.³⁹ The PRAI’s high ICC values (range: $0.87-0.96$) indicate that the variation in scores at each 2-week interval is almost exclusively due to differences between patients, rather than variability within patients.

We observed that despite the PRAI’s strong overall test-retest reliability, with all coefficients exceeding 0.70 , arthralgia severity was reported higher at baseline than at

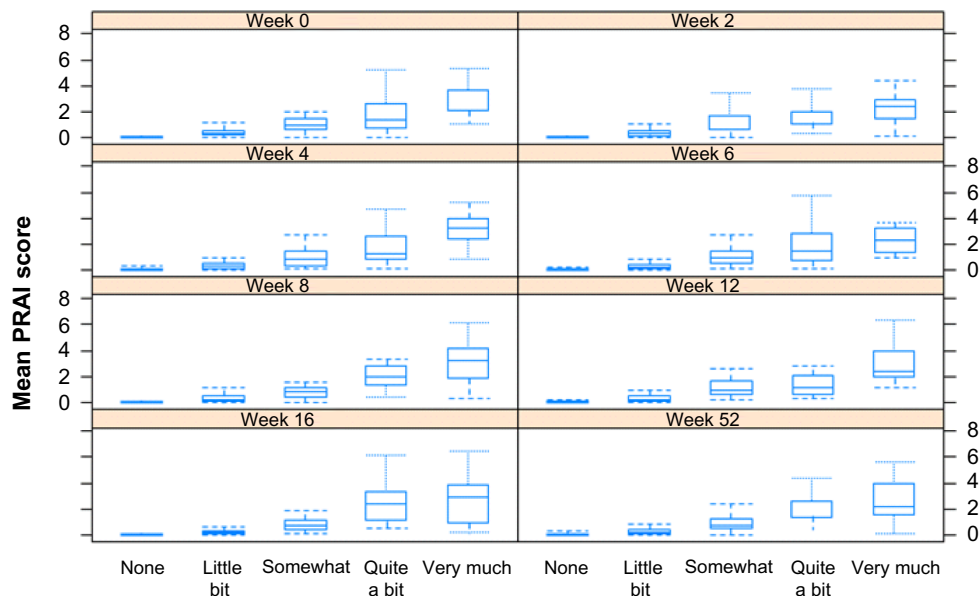

Figure 4 Mean PRAI score by response to the FACT-ES item “I have pain in my joints” over time.

Table 2 Estimated Spearman correlation between mean PRAI score and FACT-ES item “I have pain in my joints” by week

Weeks	Spearman	95% CI	P-value
0	0.82	0.78–0.87	<0.0001
2	0.80	0.74–0.85	<0.0001
4	0.76	0.69–0.83	<0.0001
6	0.80	0.75–0.85	<0.0001
8	0.82	0.77–0.87	<0.0001
12	0.82	0.76–0.86	<0.0001
16	0.81	0.73–0.87	<0.0001
52	0.79	0.72–0.85	<0.0001

Abbreviations: CI, confidence interval; FACT-ES, Functional Assessment of Cancer Therapy-Endocrine Subscale; PRAI, Patient-Reported Arthralgia Inventory.

any subsequent assessment. This resulted in less agreement between scores at weeks 0 and 2 than those at later weeks among the women without breast cancer. Mishra and Kuh similarly observed greater patient-reported menopausal symptom severity upon first assessment as compared with subsequent assessments in a general population, excluding the baseline data from their results for this reason.² In the absence of a feasible biological explanation for why symptom severity might be greater at baseline than at later assessments, future research should examine a potential pattern of greater severity the first time a symptom severity question is asked.

Our findings confirmed expectations based on past research that greater arthralgia severity as reflected by higher PRAI scores was associated with increased severity/impact of other symptoms of post menopause, aging, and illness in general as reflected by other patient-reported outcomes measures. Specifically, we observed concomitant decline

**Figure 5** Duration of morning stiffness in minutes and PRAI.

Abbreviation: PRAI, Patient-Reported Arthralgia Inventory.

in physical function, increased interference of pain with activities of daily living, reduced performance status, and increased morning stiffness among the patients with greater PRAI-measured arthralgia severity. Our finding regarding increased morning stiffness as a proxy for inflammation suggests that patients experiencing more severe arthralgia were more likely to present with patient-reported symptoms of inflammation. Further research should explore, perhaps by administering the PRAI concurrently with biomarker collection and/or rheumatology examination (including range of motion assessment), the role of arthralgia in inflammation and vice versa, so that diagnostic methods, treatments, and/or symptom-dependent decisions regarding AI therapy may be more informatively developed for and discussed with patients.

The PRAI fulfills an important clinical research need for a multi-item scale, the benefits of which for measurement are described by Nunnally and Bernstein.³⁸ Because the PRAI was developed in collaboration with patients and with experts in rheumatology, it also has good face and content validity. Our previous work with this scale also lends evidence to support its construct validity. The model-based trajectory of PRAI scores in women initiating AI therapy at baseline diverged at week 6 from the trajectory of postmenopausal women without cancer ($P < 0.01$). The trajectories also showed an increase in arthralgia severity among those taking AI therapy over the 52 weeks of per-participant observation.⁵

Our findings indicate that this instrument has satisfactory reliability and validity for use in assessing the severity of arthralgia in clinical and nonclinical/general populations. Our key results indicate strong internal consistency and test-retest reliability of the PRAI, and provide evidence of its construct validity using a multi-method approach.

Supplementary materials

Table S1 Patient-Reported Arthralgia Inventory

These questions are about pain in specific joints over the past 7 days. Please rate your pain in each joint using a number from 0 through 10, with 0 being no pain at all and 10 being the worst pain you can imagine

	0 None	1	2	3	4	5	6	7	8	9	10 As bad as you can imagine
Left finger joints?	0	1	2	3	4	5	6	7	8	9	10
Right finger joints?	0	1	2	3	4	5	6	7	8	9	10
Left wrist joints?	0	1	2	3	4	5	6	7	8	9	10
Right wrist joints?	0	1	2	3	4	5	6	7	8	9	10
Left elbow joint?	0	1	2	3	4	5	6	7	8	9	10
Right elbow joint?	0	1	2	3	4	5	6	7	8	9	10
Left shoulder joint?	0	1	2	3	4	5	6	7	8	9	10
Right shoulder joint?	0	1	2	3	4	5	6	7	8	9	10
Left hip joint?	0	1	2	3	4	5	6	7	8	9	10
Right hip joint?	0	1	2	3	4	5	6	7	8	9	10
Left knee joint?	0	1	2	3	4	5	6	7	8	9	10
Right knee joint?	0	1	2	3	4	5	6	7	8	9	10
Left ankle joints?	0	1	2	3	4	5	6	7	8	9	10
Right ankle joints?	0	1	2	3	4	5	6	7	8	9	10
Left toe joints?	0	1	2	3	4	5	6	7	8	9	10
Right toe joints?	0	1	2	3	4	5	6	7	8	9	10

Notes: Patient-Reported Arthralgia Inventory v2.0 ©Vanderbilt University. Dove Press and the authors request that persons interested in administering the PRAI in patient populations for research or clinical purposes write to the authors at information@facit.org asking permission to use the PRAI for your study or clinical care. Please include the following as briefly as possible: your scientific aims; your sample and recruitment methods; a list of your key collaborators; and your analysis plan. There is no charge to use the PRAI, but written permission must be granted via email, based on the authors' review of your plans for use of this copyrighted instrument.

Abbreviation: PRAI, Patient-Reported Arthralgia Inventory.

Patient Related Outcome Measures

Dovepress

Publish your work in this journal

Patient Related Outcome Measures is an international, peer-reviewed, open access journal focusing on treatment outcomes specifically relevant to patients. All aspects of patient care are addressed within the journal and practitioners from all disciplines are invited to submit their work as well as healthcare researchers and patient support groups.

The manuscript management system is completely online and includes a very quick and fair peer-review system. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
