Combinations of fullerene and metal oxides (MOx) are interesting, not only because they display the individual properties of fullerene and of MOx nanoparticles, but they may also exhibit synergetic properties that are advantageous for gas sensing applications. In the present work, the adsorption of some different MOxs on fullerene C_{60}, and also the NO_2 and CO sensing properties of these complexes, have been theoretically studied. All quantum mechanical computations have been carried out using Gaussian G09, employing the DFT method at the B97D/6-311G(d,p) level. NBO theory has been used for analysis of the charge transfers during gas adsorption. The chemical nature of the newly formed bonds in the studied complexes and their relative strength have been analysed using AIM2000 software. The results show that MOx/C_{60} complexes are much stronger adsorbents for NO_2 and CO than C_{60} is. It is also expected that these complexes have more optical and electrical sensitivity in the selectivity towards gases, including NO_2 and CO.

1 Introduction

Metal oxides (MOx) are widely used in environmental reconstruction and destruction of organic pollutants due to their easy accessibility, low cost and non-toxicity and excellent photocatalytic properties.[1–4] In the photocatalytic processes, the absorbed photons in MOxs form electron–hole pairs, which can react with molecules on the surface of particles and cause their destruction or degradation. Despite the high ability of MOxs to perform photocatalytic processes, some limitations prevent their widespread use in these processes. Their relatively low quantum efficiency due to the quick recombination of electron–hole pairs is among the limitations of most MOxs, especially titanium dioxide (TiO_2) and is a limiting factor in photocatalytic processes.[5] The photocatalytic activity of MOxs is improved by some modifications such as coupling with other elements, and surface coating with noble metals and other semiconductors.[6,7]

Conjugation of the MOxs with three-dimensional π systems effectively enhances the electron transfer process between them.[8] Fullerenes C_{60}, with spherical closed-shell configuration consisting of 30 bonding molecular orbitals with 60 π-electrons,[9] is suitable for conjugation with the MOxs that improves the electron transfer process and leads to the reduction of C_{60} and minimization of the structural changes.[10,11] One of the remarkable properties of the fullerenes (with a high electron-acceptor capacity) in the electron transfer processes is their ability to the quick separation of photoinduced charges, and consequently slows down the electron–hole pair recombination.[12] Therefore, conjugation of the MOxs and fullerene C_{60} provides an ideal system for more efficient electron transfer and charge separation.

MOxs, especially ZnO, have been highly regarded in the field of gas monitoring due to the high mobility of conduction electrons and their chemical and thermal stability. Detecting properties for various gases including toxic and pollutant gases (such as CO, NO_x, H_2S and SO_2) by MOx nanoparticles have been reported in many studies.[13–15] However, some factors like photo corrosion processes[16,17] and the high HOMO–LUMO energy gap[18,19] for the MOxs decrease their activity and stability, and limit their application in the gas monitoring. In addition, the operating temperature of these detectors is high, that leads to the high energy consumption and security problems related to the presence of explosive gases in the environment.[20]

Interactions between the MOxs and fullerenes can change the bond gaps of the reactants, and thereby change conductivity of the total system. The study on optical conductivity of the complex of fullerene C_{60} and TiO_2 shows that its conductivity has been significantly increased in presence of radiation.[21] Interaction between the zinc oxide particles and fullerene C_{60} enhances stability of the ZnO nanostructure in addition to increase efficient photocatalytic activities.[22] Moreover, fullerene has a high surface area that can provide more situations for more effective processes. It has been also shown that interaction between the TiO_2 nanoparticles and fullerene C_{60} reduces toxicity of the C_{60} in aquatic environments.[23]

Therefore, studying and understanding the interactions between the MOxs and fullerenes is particularly important. The researches in scientific sources express that such interactions have been only investigated for the TiO_2 and ZnO crystalline nanoparticles.[21–23] Nonetheless, investigating of the interactions between the MOxs and fullerenes at the molecular levels, understanding behaviour of the orbitals, gaining the energies and other adsorption parameters are only possible through the theoretical calculations and molecular quantum studies, which, based on our literature survey, has not been performed, yet.

In this study, molecular interactions between the ZnO (n-type semiconductor), NiO and Cu_2O (p-type semiconductors) MOxs with the fullerene C_{60} (n-type) have been theoretically studied. Adsorption energies, intermolecular distances in complex structures of the fullerene-MOx (MOx/C_{60}), energy of HOMO–LUMO surfaces and their gap, NBO charges analyses, enthalpy changes, polarizabilities and some reactivity indices in these interactions have been analysed and compared with each other.

Since the adsorbed MOxs on the fullerene C_{60} almost change the conductivity, dipole moment and the other electronic properties of the C_{60}, it is expected that the MOx/C_{60} complexes will behave different from the involved molecules (C_{60} and MOxs) in variety of the reactions including interactions with the gases.

On the other hand, the studies on adsorption and storage of the gas molecules by the fullerene C_{60} show that the gases such as N_2, Ar and CO_2 locate in the inter-cavity spaces of this spherical structure. Nevertheless, they are weakly adsorbed on the surface of C_{60}.[24] This, besides the weak adsorption of gases like CO, NO, CO_2 and N_2O on the fullerene surface, indicates that the unmodified surface of the C_{60} is not suitable for adsorption or storage of these gases.[25,26]

One of the modifications that improves the gas detection ability of the carbon structure substrates is their combination with single metal atom catalysts.[27] The carbon substrates doped with the single atom catalysts based on transition metal atoms can effectively alter the surface's local electrical neutrality and increase effective reaction sites.[27–32] For example, Luo *et al.* showed that fullerenes doped with MnN_4 catalyst efficiently adsorb toxic gases. Nevertheless, this substrate (MnN_4-C_{60}) is incapable in oxidizing gases.[27] Oxidation of a toxic gas ia a significant advantage for its sensing. MOx/C_{60} adsorbents are predicted to provide oxidation potential of toxic gases due to the presence of oxygen in their structure, in addition to their more efficient gas adsorption. Another advantage is more availability of the substrates and less difficulty of the synthesis. MnN_4-C_{60} substrates (MnN_4 doping for C atoms of C_{60}) require more time and knowledge for its synthesis, compared to that of the MOx/C_{60} exohedral fullerene adsorbents.

Based on our literature survey, there is no experimental or theoretical investigation on gas adsorption on MOx/C_{60} complexes. Studying adsorption of the NO_2 (electrophile) and CO (nucleophile) gases on the MOx/C_{60}, is another purpose of this research and could be useful in gaining the detectors with higher sensitivity and capability. NO_2 is one of the pollutants of which million tons is produced every year, and its most important sources are internal combustion engines, thermal power plants and to some extent pulp factories. Inhalation of the NO_2 gas is toxic, and long-term exposure to that has adverse effects on health.[33,34] CO is another common gas pollutant, which is produced during the combustion processes, and has adverse effects on human health and environment. Although many efforts have been made to reduce these gas pollutants,[35,36] more effective methods are still needed to eliminate them.

2 Computational methods

In the weaker interactions, such as interaction of the gases on the fullerene surfaces, dispersion forces or van der Waals forces play a major role.[37] One of the DFT based methods that includes dispersion forces in computations is B97D (or Grimm method involving dispersion).[38] In this method, the generalized gradient approximation (GGA) is used to calculate the exchange-correlation energy and can comprise electronic long-range correlations (which are responsible for the van der Waals forces) in the calculations.[38]

The geometries of all free structures, including the fullerene C_{60}, MOxs, and NO_2 and CO gases, in addition to the complexes of their interactions have been fully optimized at the B97D/6-311G(d,p) theoretical level. Harmonic vibration frequency calculations have been also performed following the geometrical optimizations to confirm the global minimums, at the same method and basis set. Interaction energies have been calculated for all complex systems and these energies have been corrected for the basis set superposition error (BSSE).[39,40] All optimizations and energy calculations in this study have been carried out using Gaussian W09 package.[41]

Analyses of natural bond orbitals (NBOs) have been done using GENNBO 5.0 software[42] to investigate the natural atomic charges, charge transfers between donor–acceptor bond orbitals, and the interaction energies between them. Gauss View 5.0 software[43] has been also used to visualize and investigate geometries and structural properties.

Chemical nature of new formed bonds in the studied complexes and their relative strength have been analysed using Atoms in Molecules (AIM) theory of Bader.[44,45] Electron density ($\rho(r_c)$) at the critical points of the bonds and its Laplacian ($\nabla^2\rho(r_c)$) for the global minimum structures have been estimated using AIM2000 software.[44] The magnitude and sign of

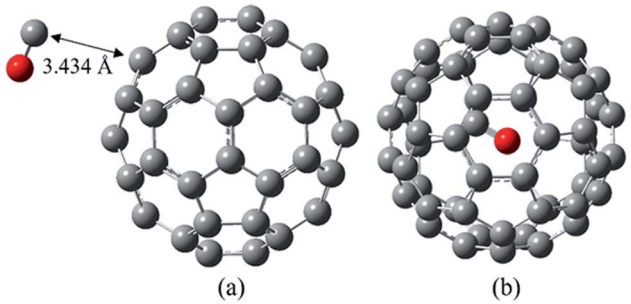

Fig. 2 The most stable complex of CO/C_{60} in two different views, at B97D/6-311G(d,p).

Table 1 N–O/C–O bond lengths (in Å) and Wiberg bond orders of NO_2, CO and the most stable complexes of NO_2/C_{60} and CO/C_{60}, calculated at B97D/6-311G(d,p) level

Structure	Bond	Bond length	Bond order
NO_2/C_{60}	N–O	1.205	1.642
CO/C_{60}	C–O	1.137	2.293
NO_2	N–O	1.203	1.650
CO	C–O	1.136	2.298

the electron density's Laplacian by specifying condensation or expulsion zones of charges is the basis for categorizing the nature of interactions.[45] Laplacian values of ρ at the r_c for atomic interactions in molecules at the equilibrium geometries have a negative sign for the systems with covalent interactions; and have relatively small values with a positive sign for weak closed-shell interactions such as van der Waals interactions.[45]

3 Results and discussion

3.1 Gases adsorption on fullerene C_{60}

Structural study. The NO_2 and CO gas molecules have been placed in different sites of the fullerene C_{60}, and the calculated structures of the most stable complexes have been shown in Fig. 1 and 2, respectively.

Calculated values of bond lengths and Wiberg bond orders for N–O and C–O bonds of the most stable complexes of NO_2/C_{60} and CO/C_{60}, together with their corresponding values for the NO_2 and CO gas molecules have been listed in Table 1. Absolute energies ($E_{abs.}$), also their corrected values for zero point energy (ZPE), of NO_2, CO and their most stable complexes with C_{60} have been given in ESI as Table S1.†

According to the optimization calculations, those NO_2/C_{60} complexes are the most unstable in which the NO_2 group has interacted with the C_{60} from the nitrogen atom side. In the most stable complex of NO_2/C_{60}, the NO_2 molecule has interacted with the C_{60} by its oxygen atoms. As shown in Fig. 1, in this structure, one of the oxygens has placed on a pentagonal ring and the other has located on a hexagonal ring of the C_{60}.

The value of 3.019 Å has been obtained for the shortest distance between the oxygen of the NO_2 and carbon atom of the C_{60}, with the Wiberg bond order of 0.010.

In the optimized NO_2 molecule, the N–O bond length and the ONO bond angle are 1.203 Å and 133.9°, respectively, which are very close to the experimental values (N–O bond length in the NO_2 molecule is 1.188 ± 0.004 Å, and the bond angle is 134.100 ± 0.250°).[46] The obtained N–O bond length of NO_2 segment in the most stable complex of NO_2/C_{60} is 1.205 Å, and its bond angle is 133.8°. In general, during the NO_2 adsorption on the C_{60}, the structural parameters of both molecules have not been significantly changed.

As shown in Fig. 2, in the most stable complex of CO/C_{60} the CO molecule has almost located on a hexagonal ring of the C_{60}. The calculated distance of the carbon atom of the CO to the nearest carbon atom of the C_{60} is 3.434 Å, with the Wiberg bond order of 0.010. According to the data of Table 1, the C–O bond length in the optimized CO molecule and also in the most stable complex of CO/C_{60} is approximately 1.136 Å, at the B97D/6-311G(d,p) computational level. In general, it could be said that during the CO adsorption on the C_{60}, the structural parameters of both molecules have been unchanged.

AIM study. For the shortest distance between the oxygen of the NO_2 and carbon atom of the C_{60} (Fig. 1), according to the AIM results, the small and positive value of the electron density's Laplacian $\nabla^2\rho$ (0.0285 a.u.) with the small value of electron density ρ (0.0089 a.u.) at the bond critical point between the two mentioned atoms indicates that their interaction is a very weak closed-shell of van der Waals type. At the critical point between the carbon atom of the CO to the nearest carbon atom of the C_{60} (Fig. 2), the calculated value of 0.0080 and 0.0028 a.u. for the $\nabla^2\rho$ and ρ, respectively, indicates a van der Waals nature of this weak interaction.

Table 2 Adsorption energies and their values with the BSSE corrections, enthalpy changes of complexation, changes of NBO charges (Δq) in NO_2 and CO after complexation, energies of HOMO and LUMO levels and their gaps for C_{60}, NO_2, CO and the most stable complexes of NO_2/C_{60} and CO/C_{60}, calculated at B97D/6-311G(d,p) level

Structure	$E_{ads.}$ (kcal mol^{-1})	$E_{ads.}$ + BSSE (kcal mol^{-1})	ΔH (kcal mol^{-1})	Δq (a.u.)	E_{HOMO} (eV)	E_{LUMO} (eV)	Gap (eV)
NO_2/C_{60}	−3.93	−2.03	−2.78	−0.011	−5.72	−4.08	1.64
CO/C_{60}	−2.15	−1.54	−4.73	0.000	−5.75	−4.09	1.66
NO_2	—	—	—	—	−6.37	−3.45	2.91
CO	—	—	—	—	−8.96	−1.76	7.20
C_{60}	—	—	—	—	−5.74	−4.08	1.66

Energy study. Values of the adsorption energies ($E_{ads.}$) with the BSSE corrections, enthalpy changes of the interactions, energies of the HOMO–LUMO levels and their gaps for the C_{60}, NO_2 and CO gases, and the most stable complex of NO_2/C_{60} and CO/C_{60} have been calculated and the results have been presented in Table 2.

The calculated $E_{ads.}$ values for adsorption of the NO_2 and CO molecules on the C_{60} are small, and even smaller with the BSSE corrections. These, beside the small values of the enthalpy changes, confirm the weakness of these interactions, in agreement with the previously discussed results of structural and AIM studies.

According to the data in Table 2, the HOMO–LUMO levels and their gap in the fullerene C_{60} have been not or negligibly changed after adsorption of the studied gas molecules.

NBO study. According to the NBO charge calculations, the total changes in charge of the NO_2 and CO molecules after their adsorption on the C_{60} (given in Table 2, as Δq) are negligible, which again indicate that these interactions are very weak. In the case of NO_2 adsorption, the small negative value of charge transfer to NO_2 is due to its high electron acceptor property.[47]

All structural, AIM, energy and NBO studies indicate that the adsorptions of the NO_2 and CO gas molecules on the C_{60} are very weak. Therefore, it is confirmed that fullerene alone cannot be a suitable adsorber or detector for the target gases.

3.2 Gases adsorption on the MOxs

Structural study. In order to obtain the most stable complex structures of the NO_2/MOx and CO/MOx, all possible structures for placing of the NO_2 and CO molecules on the studied MOxs have been considered, and the most stable structures have been identified. These structures for the NO_2/MOx and CO/MOx have been shown in Fig. 3 and 4, respectively.

Also, the calculated values of the selected bond lengths and their Wiberg bond orders for the mentioned most stable complexes, together with those corresponding values of the MOx have been given in Table 3. The obtained $E_{abs.}$ values with the ZPE corrections for these complexes have been given in Table S1.†

According to Fig. 3(a), for the most stable structure of NO_2/Cu_2O complex, each of the copper atoms has located in adjacent to one of the oxygen atoms of the NO_2 gas, with a distance of 1.907 Å and a bond order of 0.223. In the most stable structure of NO_2/ZnO complex, Fig. 3(b), ZnO has been approached to the oxygen atoms of NO_2 from the Zn side. This is in agreement with the findings of Spencer *et al.* in their theoretical study on adsorption of the NO_2 on the ZnO nanowires.[48] As shown in the Fig. 3 and Table 3, the distances of the Zn atom to the oxygen atoms are 1.960 and 2.290 Å. In the case of the most stable structure of NO_2/NiO complex, as shown in Fig. 3(c), NO_2 has interacted with the Ni atom more closely from its nitrogen side. Previously, Wang *et al.* studied adsorption of the NO_2 molecule on a surface of NiO using molecular simulation and DFT methods, and understood that the strongest interaction occurs when NO_2 approaches to the NiO surface from its N atom side.[49]

According to the data in Table 3, the bond lengths of N–O in the structure of all NO_2/MOx complexes have been slightly increased in comparison to that in the NO_2 free molecule. The lengths of metal–oxygen bond of MOx in both complexes of NO_2/Cu_2O and NO_2/ZnO are slightly higher than their corresponding values in the Cu_2O and ZnO molecules. These could be due to weak donor–acceptor interactions in the NO_2/Cu_2O

	Ni4–C1	1.802	0.707
	C1–O3	1.283	1.384
	C1–O2	1.197	1.786
Cu_2O	Cu–O	1.766	0.795
	Cu–Cu	2.957	0.158
ZnO	Zn–O	1.776	0.992
NiO	Ni–O	1.673	1.030

and NO_2/ZnO complexes. Whereas for the most stable complex of NO_2/NiO, with the relatively good donor–acceptor interactions, the Ni–O bond length is shorter than that in the NiO molecule.

According to Fig. 4(a) at the most stable structure of CO/Cu_2O complex, the CO has been approached to the Cu atom from its carbon atom side, with a distance of 1.743 Å and a bond order of 0.834.

In the most stable form of CO/ZnO complex (Fig. 4(b)), interestingly, the adsorption is more a chemical interaction, which the CO molecule has adsorbed the oxygen atom of the ZnO, and thereby, a CO_2 molecule has been produced and Zn (with a partial charge of 0.009) released. The ZnO nanoparticles oxidize their adjacent species by creation of oxygen active species and have been always studied as a toxic MOx in biological and health issues.[50,51] The rapid and strong interaction of carbon monoxide gas on the MOx substrate of ZnO and the releasing of CO_2 gas has been demonstrated in various experiments.[52]

In the case of CO/NiO complex, the CO molecule has been approached to the NiO from its carbon side. The values of bond lengths and bond orders in this complex have been given in the Fig. 4(c) and Table 3. In this structure, the O3 of NiO is very close to the CO molecule and bonds with it (with a bond length of 1.283 Å and bond order of 1.384), but (unlike to the CO complex with ZnO) its affinity for bonding with the Ni prevents releasing of CO_2.

According to the data in Table 3, the length of the CO bond in complex with the target MOxs has become slightly longer than that in the free CO molecule (which is 1.136 Å). The metal and oxygen atoms distances of MOxs in both complexes of CO/ZnO and CO/NiO are higher than their corresponding values in the ZnO and NiO molecules. However, for the complex of CO/Cu_2O, the Cu–O bond length is shorter than that in the Cu_2O molecule, which may be due to the notable donor–acceptor interaction from lone pair (LP) of O3 to σ* of C1–Cu4 bond (78.98 kcal mol^{-1}).

AIM study. The values of $\nabla^2\rho$ for all bond critical points between the atoms involved in the interactions of gas molecules with metal oxides have been calculated. In the case of the NO_2/Cu_2O complex, no critical point has been detected by the AIM software at the distance between the NO_2 oxygen atoms and the Cu atoms (the involved atoms in the interaction in Fig. 3(a)). In the most stable complex of NO_2/ZnO, the calculated values of $\nabla^2\rho$ at the critical points between the Zn atom to the O2 and O3 atoms (Fig. 3(b)) are 0.1433 (ρ = 0.0408 a.u.) and 0.4002 (ρ = 0.0876 a.u.), respectively. These values, together with the values of $\nabla^2\rho$ and ρ at the critical point between Ni and nitrogen atoms in NiO/NO_2 (0.6491 and 0.1548 a.u., respectively), show significant van der Waals type interactions between the NO_2 gas molecule and the studied metal oxides.

According to the AIM calculations, in the most stable structure of CO/Cu_2O complex, the value of $\nabla^2\rho$ at the critical point between Cu4 and carbon atom is 0.6340 (ρ = 0.1583 a.u.), which indicates a significant van der Waals type interaction between the two molecules. In the case of CO/ZnO, the $\nabla^2\rho$ value at the critical point of the C1═O4 bonds (about −0.0174 with ρ = 0.4461 a.u.) can be considered as a confirmation of the covalent type interaction here. For the CO/NiO complex, the calculated $\nabla^2\rho$ values at the critical points between the Ni–C and O3–C bonds are respectively 0.2945 (ρ = 0.1560 a.u.) and −0.3894 (ρ = 0.3466 a.u.). The negative value of $\nabla^2\rho$ (with the acceptable value of ρ) indicates a covalent interaction between the CO molecule and the oxygen of NiO.

Energy study. The calculated adsorption energies, the enthalpy changes of complexation, energies of the HOMO–LUMO levels and their gaps for the MOxs, and the most stable NO_2/MOx and CO/MOx complexes have been listed in Table 4.

In general, the calculated energies for adsorption of the NO_2 and CO on the studied MOxs, in comparison with their adsorption on the C_{60} (Table 2), show much larger values. In addition, the high values of enthalpy changes for adsorption of these gas molecules on the MOxs, compared to those values in the C_{60}, are another confirmation of strength of these interactions. Enthalpy changes with a negative sign also indicate that these adsorption processes are exothermic. $E_{ads.}$ data in the Table 4 show that NiO is a much stronger adsorbent for the NO_2 and CO than the two other MOxs.

According to the data in Table 4, the energy values of HOMO and LUMO levels and the gaps between them in the complexes of NO_2/MOx and CO/MOx have been significantly changed in comparison with those in the corresponding MOxs.

Table 4 Adsorption energies and their values with the BSSE corrections, enthalpy changes of complexation, changes of NBO charges (Δq) in NO_2 and CO after complexation, energies of HOMO and LUMO levels and their gaps for the MOxs, and the most stable complexes of NO_2/MOx and CO/MOx, calculated at B97D/6-311G(d,p) level

Structure	$E_{ads.}$ (kcal mol^{-1})	$E_{ads.}$ + BSSE (kcal mol^{-1})	ΔH (kcal mol^{-1})	Δq (a.u.)	E_{HOMO} (eV)	E_{LUMO} (eV)	Gap (eV)

NiO	—	—	—	—	−1.25	−0.59	0.66

NBO study. The NBO charge calculations on the complexes of NO_2/MOx have indicated that the total charge of NO_2 molecule has become negative after adsorption on the MOxs, indicating the electron transfer from the MOxs to the NO_2. Amount of this charge transfer (Δq in Table 4) is very significant, compared to the amount of electrons that C_{60} transfers to NO_2 gas molecule during their interaction (−0.011 a.u.). According to the results of the previous section, the NiO interacts more strongly with the NO_2 compared to the other two MOxs. Therefore, more charge transfer is expected during this adsorption process. However, according to the data in Table 4, the amount of charge that NO_2 receives from the NiO surface during their interaction is less than that of the other two MOxs. This could be explained by considering the involved atoms in these interactions. As mentioned, NO_2 interacts with the NiO from its nitrogen side, and with the ZnO and Cu_2O from its oxygen atoms. Since nitrogen has less electronegativity than oxygen, NO_2 receives less electron from the NiO surface, compared to the ZnO and Cu_2O surfaces during adsorption on them.

According to the NBO calculation, the most notable donor–acceptor interactions in the complex of NO_2/NiO are from LP of Ni4 to σ* of N1–O3 (7.17 kcal mol^{-1}), and from LP of O5 to σ* of N1–Ni4 (12.22 kcal mol^{-1}). In the case of the other two complexes (NO_2/Cu_2O and NO_2/ZnO) no significant interaction is observed in the NBO calculations.

In the complex of CO/Cu_2O, 0.256 a.u. of charge has been transferred from Cu_2O to the CO unit (according to the NBO charges calculations), and the total charge of CO molecule has become negative after adsorption on the Cu_2O. The ZnO molecule has donated its oxygen atom to the CO during the interaction with it, and a neutral CO_2 molecule has been produced. The calculated initial charge of CO unit in the produced CO_2 molecule is 0.468 a.u., which indicates oxidation of CO against ZnO. In the complex of CO/NiO, the CO molecule has become similar to a CO_2 molecule by forming a new bond with the oxygen of NiO, but the tendency of this oxygen to keep a bond with the Ni has prevented releasing of CO_2. Therefore, the oxidation process here is weaker than that in the CO/ZnO and is associated with lower charge transfer. In general, the charge transfer between the MOxs and CO is much more significant compared to the amount of charge (near to zero) that C_{60} transfers to this gas molecule during their interaction.

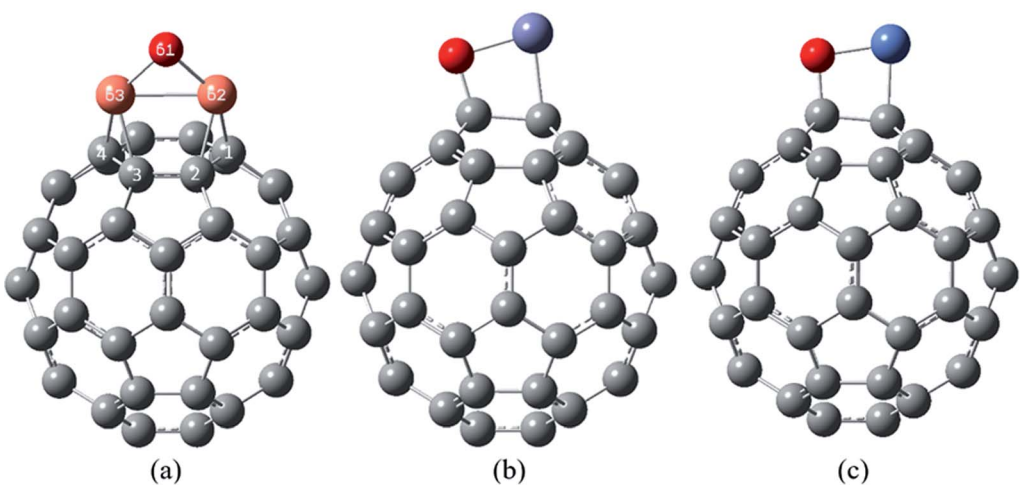

Fig. 5 The most stable complexes of (a) Cu_2O/C_{60}, (b) ZnO/C_{60} and (c) NiO/C_{60}, at B97D/6-311G(d,p).

Table 5 Involved bond lengths (in Å), Wiberg bond orders, in the C_{60} and the most stable complexes of MOx/C_{60}, calculated at B97D/6-311G(d,p) level

Structure	Bond	Bond length	Bond order
Cu_2O/C_{60}	Cu–O	1.817	0.493
	Cu–Cu	2.443	0.037
	Cu–C	1.970	0.295
	C–C	1.489	1.082
	C=C	1.456	1.194
ZnO/C_{60}	Zn–O	1.944	0.282
	Zn–C	2.122	0.424
	O–C	1.408	0.994
	C–C	1.612	0.947
NiO/C_{60}	Ni–O	1.762	0.664
	Ni–C	1.847	0.621
	O–C	1.435	0.925
	C–C	1.563	0.939
C_{60}	C–C	1.454	1.162
	C=C	1.401	1.368

As the NBO calculations show the most significant donor–acceptor interactions in the CO/Cu_2O complex is from LP of O3 to σ* of C1–Cu4 (78.98 kcal mol^{-1}). The strongest donor–acceptor interactions in the most stable complex of CO/ZnO are from LP of O2 to π* of C1–O4 (102.87 kcal mol^{-1}) and to σ* of C1–O4 (103.27 kcal mol^{-1}). In the case of CO/NiO complex, the strongest donor–acceptor interactions are from LP of O2 to σ* of C–Ni (49.77 kcal mol^{-1}) and to σ* of C–O3 (12.81 kcal mol^{-1}), and from LP of O3 to σ* of C–O2 (62.68 kcal mol^{-1}).

The changes in the HOMO–LUMO levels energies of metal oxides before and after adsorption of gas molecules, along with the high values of $E_{ads.}$, notable charge transfers during interactions, and significant changes in the enthalpy values indicate the strong interactions of the NO_2 and CO molecules with the studied MOxs. All calculations have shown that both studied gas molecules have stronger adsorption on NiO, compared to the other two MOxs.

3.3 Gases adsorption on MOx/C_{60}

3.3.1 MOx/C_{60} complexes

Structural study. The target Cu_2O, ZnO and NiO metal oxides have been placed in different sites of the fullerene C_{60} (on pentagonal and hexagonal rings, on single bonds (between pentagonal and hexagonal rings) or double bonds (between two hexagonal rings)). The most stable structure for each complex of the MOx/C_{60} (shown in Fig. 5) have been identified by calculating the $E_{ads.}$ Harmonic vibrational frequency calculations following all the optimization calculations show that all frequencies have positive values. The calculated values of the bond lengths and Wiberg bond orders for the new formed bonds of the most stable MOx/C_{60} complexes, along with those values for the initial C_{60} have been listed in Table 5. The obtained $E_{abs.}$ values for these complexes have been also given in Table S1.†

The most stable structure of the Cu_2O/C_{60} complex has been shown in Fig. 5(a). In this complex the Cu_2O molecule has located on a hexagonal ring of the C_{60}, and each of the Cu atoms has formed a quasi-trigonal ring with the atoms of the double bonds of the hexagonal ring (the bonds between hexagonal rings). This is consistent with the reports on exohedral cuprofullerenes.[53–55] The adsorption of Cu_3 units on the C_{60} fullerene demonstrates that each of the Cu atoms bridges on a double bond of the C_{60} and forms a trigonal. This trend continues until the increase of eight Cu_3 units and synthesis of $C_{60}@Cu_{24}$.[53,54] Also, according to the calculations, in the complex of Cu_2O/C_{60}, the Cu–O bond length is 1.817 Å, which is higher than that in a Cu_2O free molecule (1.766 Å).

In the most stable complex of ZnO/C_{60}, Fig. 5(b), the ZnO molecule has been placed exactly parallel to a bond between two hexagonal rings of the fullerene C_{60}, and has formed a quasi-tetragonal ring with the atoms of this C=C bond. According to the data in Table 5, the Zn–O bond in this complex has a calculated length of 1.944 Å, which is much longer than that in the ZnO free molecule (1.776 Å). The calculated length of new formed bonds of Zn–C and O–C in this complex are 2.122 and 1.408 Å, respectively.

Fig. 5(c) shows the most stable structure of NiO/C_{60} complex, in which NiO (like ZnO) has posited in parallel with a C=C bond between two hexagonal rings of the C_{60}. According to the data in Tables 3 and 5, the Ni–O bond length in this complex is longer than this corresponding value in the NiO molecule. The bond lengths of Ni–C and O–C in this complex are respectively 1.847 and 1.435 Å.

AIM study. The values of ρ and $\nabla^2\rho$ at all bond critical points between the atoms involved in the interactions of the MOxs and

Table 6 Binding energies and their values with the BSSE corrections, enthalpy changes of complexation, changes of NBO charges (Δq) in MOx after complexation, ionization potential, energies of HOMO and LUMO levels and their gaps for the MOxs, and the most stable complexes of MOx/C_{60}, calculated at B97D/6-311G(d,p) level

Structure	$E_{b.}$ (kcal mol^{-1})	$E_{b.}$ + BSSE (kcal mol^{-1})	ΔH (kcal mol^{-1})	Δq (a.u.)	IP (eV)	E_{HOMO} (eV)	E_{LUMO} (eV)	Gap (eV)
Cu_2O/C_{60}	−89.26	−56.07	−89.02	0.903	6.50	−4.84	−4.14	0.70
ZnO/C_{60}	−66.93	−45.31	−66.44	0.191	6.72	−5.27	−4.18	1.09
NiO/C_{60}	−129.42	−65.75	−128.61	0.129	6.36	−4.68	−3.99	0.69
Cu_2O	—	—	—	—	6.25	−3.23	−2.28	0.95
ZnO	—	—	—	—	7.84	−3.69	−3.60	0.09
NiO	—	—	—	—	5.43	−1.25	−0.59	0.66

the C_{60} have been obtained and analysed. In the most stable structure of Cu_2O/C_{60} complex, the values of $\nabla^2\rho$ and ρ at the bond critical points between the Cu atoms and the carbon atoms involved in the interaction (Fig. 5(a)) are 0.2313 and 0.0974 a.u., respectively. In the ZnO/C_{60} complex structure, the values of $\nabla^2\rho$ and ρ at the bond critical point between the oxygen and the nearest carbon atom of the C_{60} are respectively −0.6537 and 0.2748 a.u. The values of $\nabla^2\rho$ at the bond critical points between Ni and oxygen of the MOx and the nearest carbon atoms in the NiO/C_{60} complex are 0.1764 (ρ is 0.1378 a.u.) and −0.5692 (ρ is 0.2568 a.u.), respectively.

Accordingly, it can be said that the positive values of $\nabla^2\rho$ at the bond critical points between the metal-carbon show van der Waals type interactions; and relatively large and negative values of $\nabla^2\rho$ (with larger values of ρ) at the critical points between oxygen–carbon bonds display significant covalent type interactions in the studied complexes.

Energy study. The binding energies (E_b) and their corrected values for the BSSE, interaction enthalpy changes (ΔH), ionization potential (IP), energies of HOMO–LUMO and their gaps for the MOxs and the most stable MOx/C_{60} complexes have been given in Table 6.

Comparison of the ionization potential values of the MOxs before adsorption on the C_{60} in Table 6 shows that the first ionization energy for the NiO is less than that for the other studied MOxs, therefore the NiO more easily donates electron to the C_{60} and makes stronger interaction with it.

As data in the tables show, energy of the HOMO–LUMO levels in the complexes of MOx/C_{60} are more similar to those in the C_{60} (Table 2) in comparison with those in the MOxs. Since the fullerene C_{60} receives the electrons from the MOxs surfaces during interaction with them, its LUMO orbital surface is expected to be involved in the interaction with the MOxs. However, since the C_{60} molecule is several times larger than the studied MOxs, its LUMO surface have not been significantly changed in the interaction with the HOMO surface of the MOxs.

Comparison between the energies of the HOMO surfaces in the MOx/C_{60} complexes shows that the HOMO surface energy in the NiO/C_{60} complex (as the most stable complex of the studied MOx/C_{60} complexes) relative to the HOMO in NiO has more changed in comparison with the other two cases. On the other hand, according to the data in Table 6, comparison of the calculated values of the HOMO–LUMO gaps in the fullerene C_{60} (1.66 eV) and those in the MOx/C_{60} complexes displays that the ZnO/C_{60} complex (which is the most unstable MOx/C_{60} complex) has less difference than the other two cases.

NBO study. Analysis of the NBO charges shows that the MOxs of the Cu_2O, ZnO and NiO have transferred a little charge to the fullerene C_{60} during interaction with it, and their total charges have become positive compared to the neutral forms before the interactions. Because NiO has a stronger interaction with the C_{60} than the other MOxs, more charge transfer during this interaction is expected. However, according to the data of Table 6, the charge transfer from the NiO to the C_{60} surface is less than that from the other two MOxs. Electron transfer process in an interaction depends extensively on the electronegativity, charge and valence electrons of the involved atoms in the interaction. The NiO and ZnO have interacted with the C_{60} by a metal atom and a non-metal electronegative oxygen atom, whereas Cu_2O has participated in the interaction through two metal atoms.

The most significant donor–acceptor interactions in the Cu_2O/C_{60} complex, are from LP of O61 to LP* of Cu62 and Cu63 atoms (that energies of both interactions are 132.51 kcal mol^{-1}),

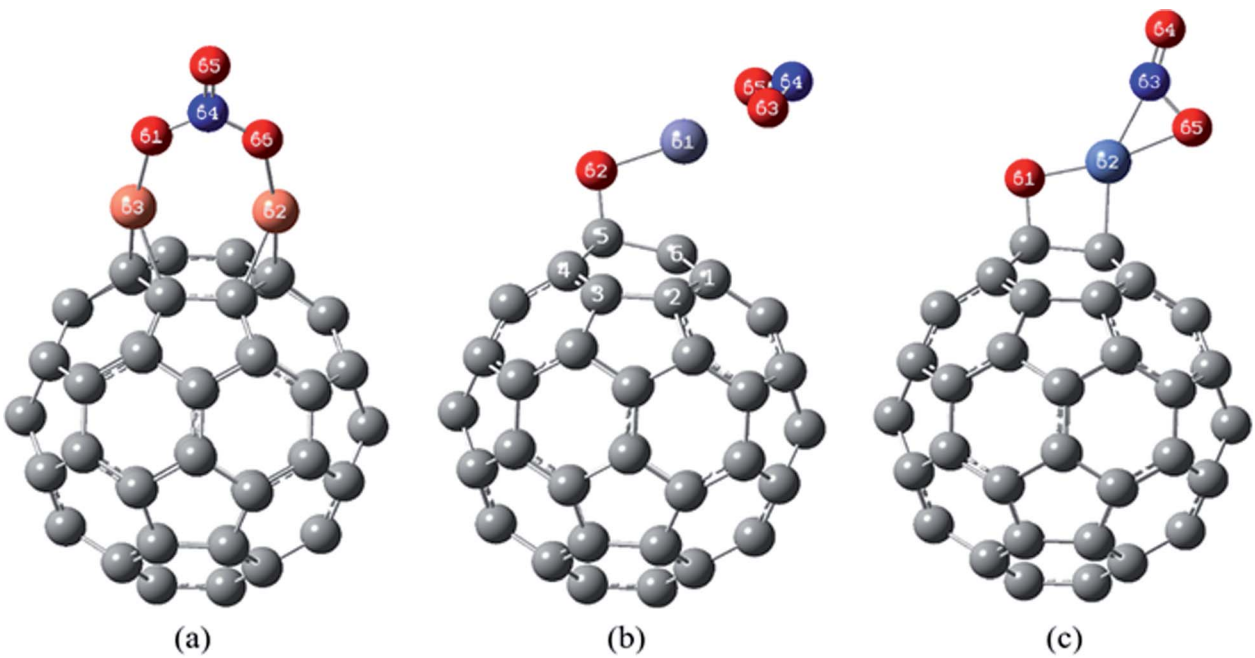

Fig. 6 The most stable complexes of (a) $NO_2/Cu_2O/C_{60}$, (b) $NO_2/ZnO/C_{60}$ and (c) $NO_2/NiO/C_{60}$, at B97D/6-311G(d,p).

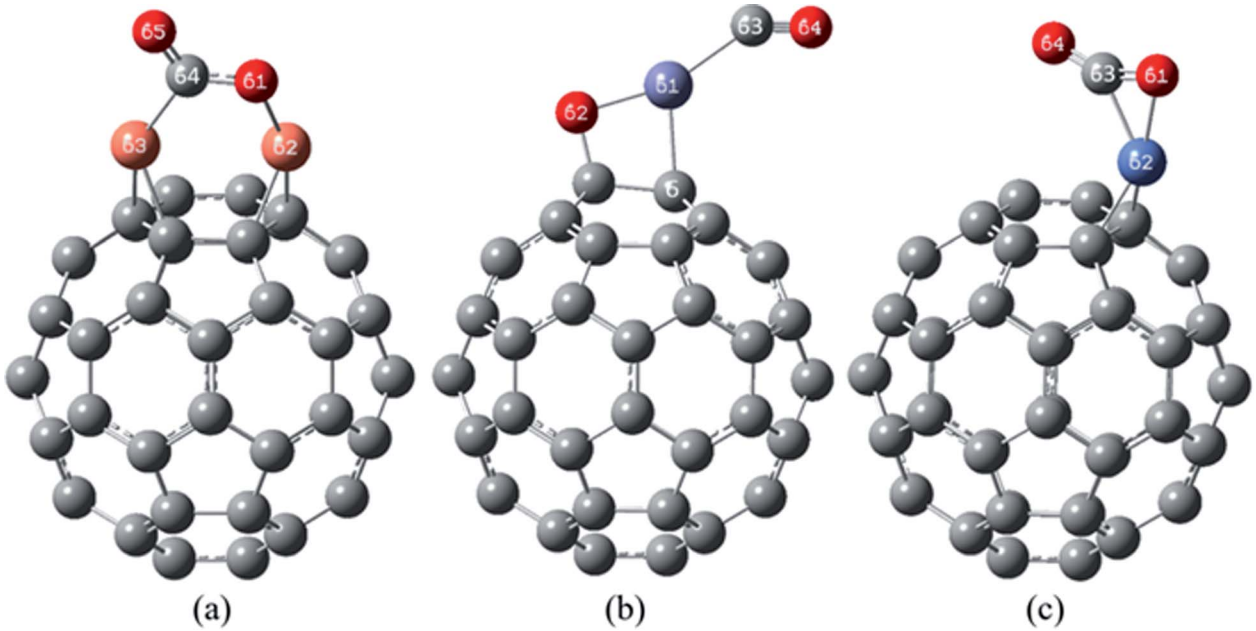

Fig. 7 The most stable complexes of (a) $CO/Cu_2O/C_{60}$, (b) $CO/ZnO/C_{60}$ and (c) $CO/NiO/C_{60}$, at B97D/6-311G(d,p).

also from LP of Cu62 and Cu63 atoms to π* of C1–C2 and C3–C4 bonds, respectively (both 20.12 kcal mol^{-1}). The strongest donor–acceptor interactions in the most stable complex of ZnO/C_{60} are from LP of O to σ* of Zn–C and to σ* of C–C bonds, also from σ* of Zn–C bond to π* of C–C bonds (27.37, 30.93 and 16.24 kcal mol^{-1}, respectively). In the case of NiO/C_{60} complex, the strongest donor–acceptor interactions are from σ* and σ of Ni–O bond to σ* of Ni–C bond, from σ of Ni–C bond to π* of C–C bonds, and from LP of O to σ* of C–C bonds (20.66, 12.36, 19.98 and 13.16 kcal mol^{-1}, respectively).

Consequently, the high E_bs, notable charge transfers, and significant changes in the enthalpy, and the HOMO–LUMO values of the fullerene C_{60} after adsorbing the studied MOxs confirm their strong interactions. According to the mentioned calculations, the NiO/C_{60} complex is more stable than the Cu_2O/C_{60} and ZnO/C_{60} complexes.

3.3.2 Gases adsorption on the MOx/C_{60}

Structural study. In order to obtain the most stable structures of $NO_2/MOx/C_{60}$ and $CO/MOx/C_{60}$ complexes, all possible structures for placing the NO_2 and CO molecules relative to the MOx/C_{60} complexes have been considered. After optimization calculations and analysing the calculated adsorption energies for all possible structures, the given structures in Fig. 6 and 7 have been obtained as the most stable complexes.

The selected bond lengths values and their Wiberg bond orders have been given in Table 7 (and the calculated $E_{abs.}$ values have been summarized in Table S1†).

In the most stable structure of $NO_2/Cu_2O/C_{60}$ complex, Fig. 6(a), adsorption of the NO_2 molecule causes a significant change in the initial structure of Cu_2O/C_{60}. The two Cu atoms have formed quasi-trigonal rings with the atoms of the bonds between hexagonal rings, and oxygen atom of the Cu_2O (O61 atom) has interacted with the nitrogen atom of the NO_2 in a way that the NO_2 molecule is oxidized to NO_3. This process can significantly reduce the volume of the NO_2 toxic gas, which is not observed in the interaction of the NO_2 on the Cu_2O.

Structure (b) in Fig. 6 shows the most stable complex of $NO_2/ZnO/C_{60}$, in which (similar to the most stable complex of NO_2/ZnO) NO_2 has been approached to the Zn atom from the oxygen atoms side. The distance between the Zn atom and the nearest carbon atom of the C_{60} is 2.370 Å, which has become higher than the length of Zn–C bond in the most stable complex of ZnO/C_{60} (2.122 Å).

The most stable structure of $NO_2/NiO/C_{60}$ complex has been shown in Fig. 6(c). Based on data comparison in Tables 5 and 7, in this complex, NO_2 adsorption has not significantly changed the initial structure of NiO/C_{60} and only the length of C–Ni bond has been slightly increased. In this complex NO_2 interacts with the Ni atom through the nitrogen and one of the oxygen atoms. The values of the bond lengths and bond orders for the new formed bonds have been given in Table 7.

In the most stable structure of $CO/Cu_2O/C_{60}$ complex (Fig. 7(a)), adsorption of a CO molecule, like NO_2, has significantly changed the initial structure of Cu_2O/C_{60}. In the mentioned structure, the CO molecule has approached the Cu_2O from the carbon side. The two Cu atoms have formed quasi-trigonal rings with the atoms of C=C bonds between hexagonal rings. One of Cu–O bond of Cu_2O/C_{60} has been broken, and the carbon atom of the CO has placed between these Cu and O atoms, making new bonds with both of them (the characteristics of these bonds have been given in Table 7). During this desirable process, the CO gas has relatively changed into the oxidized form of CO_2.

The most stable complex of $CO/ZnO/C_{60}$ has been shown in Fig. 7(b). The figure, along with the data from Tables 5 and 7 demonstrate that the initial structure of the ZnO/C_{60} has been

Table 7 Bond lengths (in Å), Wiberg bond orders, in the most stable complexes of NO_2/MOx/C_{60} and CO/MOx/C_{60}, calculated at B97D/6-311G(d,p) level

Structure	Bond	Bond length	Bond order

	Ni62–C	1.929	0.393

maintained after CO adsorption. The distances of Zn and O atoms to carbon atoms of the C_{60} in CO/ZnO/C_{60} are greatly comparable to those in the most stable complex of the ZnO/C_{60}. In this structure, the CO molecule has interacted with the Zn atom from the carbon atom side, and the distance between Zn and carbon of the CO is 2.009 Å (with a bond order of 0.347).

Fig. 7(c) shows the most stable structure of CO/NiO/C_{60} complex. According to the data of Tables 5 and 7, in this structure, adsorption of the CO causes significant changes in the initial structure of NiO/C_{60} (Fig. 5(c)). In the mentioned structure, the NiO has interacted with the C_{60} only by its Ni atom in such way that has formed a quasi-trigonal ring with the carbon atoms of a C=C bond between two hexagonal rings of the C_{60}. The CO molecule has approached the NiO molecule from its carbon side and has interacted extensively with the both O and Ni atoms. In this complex, the distance between the carbon atom of CO to the oxygen atom of the NiO/C_{60} unit is 1.253 Å (with bond order of 1.496), which indicates the strong interaction of the CO molecule with the complex of NiO/C_{60} and the relatively oxidation of the CO to the CO_2.

AIM study. The values of ρ and $\nabla^2\rho$ at all bond critical points between the atoms involved in the interactions of the target gas molecules and the MOx/C_{60} have been analysed. In the NO_2/Cu_2O/C_{60} complex, according to the obtained data from the AIM calculations, the $\nabla^2\rho$ value at the critical point of the bond between the N and the O61 (of the metal oxide) is exactly equal to that between the N and the O66 (of the initial NO_2). The magnitude and sign of the mentioned Laplacian (−0.5760, with $\rho = 0.4093$ a.u.) confirm two strong covalent interactions.

In the most stable complex of NO_2/ZnO/C_{60}, the $\nabla^2\rho$ value for the bond between the Zn and the oxygen of NO_2, which is 0.2529 (with $\rho = 0.0637$ a.u.), shows a van der Waals type interaction between the NO_2 and ZnO/C_{60} in this complex.

In the case of NO_2/NiO/C_{60} complex, the $\nabla^2\rho$ value at the bond critical point between the Ni and the N atoms is 0.4779 ($\rho = 0.0966$ a.u.).

In the most stable structure of CO/Cu_2O/C_{60} complex, the value of $\nabla^2\rho$ at the critical point of C64–O61 bond is −0.4466 ($\rho = 0.3139$ a.u.). These magnitude and sign indicate a strong covalent interaction in this gas adsorption.

In the CO/ZnO/C_{60} complex, the $\nabla^2\rho$ and ρ values (0.2175 and 0.0884 a.u., respectively) at the bond critical point between carbon atom of the gas molecule and the Zn of the metal oxide show a van der Waals type interaction between CO and ZnO/C_{60}.

For the CO/NiO/C_{60} complex, the calculated values of $\nabla^2\rho$ at the critical points of Ni–C63 and O61–C63 bonds (in Fig. 7(c)) are respectively 0.2429 ($\rho = 0.1189$ a.u.) and −0.3324 ($\rho = 0.3701$ a.u.), that the negative value of $\nabla^2\rho$ (with relatively large value of ρ) also confirms the strong covalent interaction between the carbon of the CO gas and the oxygen of the NiO metal oxide.

Energy study. The values of $E_{ads.}$ with the BSSE corrections, the enthalpy changes, energies of the HOMO–LUMO levels and

Table 8 Adsorption energies and their values with the BSSE corrections, enthalpy changes of complexation, changes of NBO charges (Δq) in NO_2 and CO after complexation, energies of HOMO and LUMO levels and their gaps for the most stable complexes of NO_2/MOx/C_{60} and CO/MOx/C_{60}, calculated at B97D/6-311G(d,p) level

Structure	$E_{ads.}$ (kcal mol^{-1})	$E_{ads.}$ + BSSE (kcal mol^{-1})	ΔH (kcal mol^{-1})	Δq (a.u.)	E_{HOMO} (eV)	E_{LUMO} (eV)	Gap (eV)

their related gaps for the most stable complexes of NO_2/MOx/C_{60} and CO/MOx/C_{60} have been calculated and the results have been summarized in Table 8.

The calculated energies for adsorption of the NO_2 and CO gases on the studied complexes of MOx/C_{60} show the much bigger values, compared to the values of the adsorption energies of these gas molecules on the C_{60} (Table 2). The high values of enthalpy changes in these interactions are also another confirmation of the strength of these adsorption processes compared to those that occur on the C_{60}. Moreover, these enthalpy changes with negative sign indicate that these adsorption processes are exothermic.

According to the calculated Δq in Table 8, during gas adsorptions on the MOx/C_{60}, some charge transfer is occurred from the MOx/C_{60} to the gases. For this, the LUMO of the NO_2 is involved in the interaction with the HOMOs of the MOx/C_{60} complexes. According to the data in Tables 6 and 8, after NO_2 adsorption, the energy changes in the HOMO levels of the MOx/C_{60} complexes are more than that in their LUMO levels, which is in agreement with the charge transfer from the HOMO of the MOx/C_{60} complexes. According to the calculated data, in comparison to the other two MOx/C_{60} complexes, the HOMO level in the NiO/C_{60} complex is closer to the LUMO level of the NO_2 molecule, which results in a stronger interaction between them. The changes in energy of the HOMO surfaces and the HOMO–LUMO gaps in MOx/C_{60} complexes, after NO_2 adsorption, are much more significant in comparison with the corresponding changes in the C_{60} (Table 2).

According to data in Tables 6 and 8, in comparison to the other CO/MOx/C_{60} complexes, both HOMO and LUMO levels in the CO/NiO/C_{60} complex have become more stable during gas adsorption. The change in the HOMO–LUMO gap value before and after CO adsorption on the NiO/C_{60} complex is also greater than those on the other MOx/C_{60} complexes, which confirm the stronger adsorption of this gas molecule on the NiO/C_{60} complex.

NBO study. According to the NBO charge changes, given in Table 8, the total charge of the NO_2 molecule has become negative after adsorption on the MOx/C_{60} complexes, which indicates the electron transfer from these complexes to the NO_2. Because the NiO/C_{60} has a stronger interaction with the NO_2 than the other MOx/C_{60} complexes, more charge transfer is expected during this adsorption process. However, according to the Table 8, the charge transfer for the interaction of NO_2 with ZnO/C_{60} is higher than the other two cases. As mentioned, NO_2 has interacted with the ZnO/C_{60} from the oxygen atoms side. Since oxygen has a high electronegativity, NO_2 receives more electrons from the ZnO/C_{60} surface during adsorption on it. Comparison between the ionization potential of MOx/C_{60} complexes before NO_2 adsorption in Table 6 shows that the IP for NiO/C_{60} is lower than those for the other MOx/C_{60} complexes, and therefore NiO/C_{60} more easily donates its first electron to the NO_2 and interacts more strongly with it.

Based on the NBO results, donor–acceptor interactions are in agreement to the charge transfers during these processes, and confirm the changes of atomic charges. The most notable donor–acceptor interactions in the complex of NO_2/Cu_2O/C_{60} are from LP of O61 and O66 atoms to σ* of N64–O65 bond (both 28.76 kcal mol^{-1}). In the case of NO_2/ZnO/C_{60} complex the most significant interactions is from LP of O62 atom to LP* of Zn61 atom (34.00 kcal mol^{-1}). These interactions in the NO_2/NiO/C_{60} are from LP of O61 atom to LP* of Ni62, from σ* of C–Ni62 to LP* of Ni62 atom, and from LP of O65 to σ* of N63–O64 (36.66, 22.03 and 26.27 kcal mol^{-1}, respectively).

In the complexes of CO/Cu_2O/C_{60} and CO/ZnO/C_{60}, the electrons has been transferred to the CO gas throughout the bond formed between its C atom and the metal atom of the MOx, and (according to the NBO charge calculations) the total charge of the CO molecule has become negative after adsorption on the Cu_2O/C_{60} and ZnO/C_{60} complexes. In the complex of CO/NiO/C_{60}, the CO molecule has reasonably changed into a CO_2 molecule by creating a strong covalent bond with the oxygen (non-metal) atom of the NiO, but tendency of the mentioned oxygen to keep a bond with the Ni prevents releasing of that as the free CO_2.

According to the NBO calculations, donor–acceptor interactions also confirm the charge transfer processes. Interactions from LP of O61 atom to π* and to σ* of C64–O65 bond (14.11 and 26.01 kcal mol^{-1}, respectively) in the CO/Cu_2O/C_{60}, and from σ* of C6–Zn61 to LP* of C63 atom (47.64 kcal mol^{-1}) in the CO/ZnO/C_{60} are some examples. In the complex of CO/NiO/C_{60}, the most notable interactions are from LP of O64 atom to σ* of Ni62–C63 bond, from σ* of Ni62–C63 to LP* of Ni62 atom (97.71 and 60.38 kcal mol^{-1}, respectively), and from LP of O61 atom to σ* of C63–O64 and Ni62–C63 bonds (71.57 and 67.52 kcal mol^{-1}, respectively).

Table 9 Calculated values of polarizability (α) and HOMO–LUMO gap for C_{60}, MOxs and the most stable complexes of MOx/C_{60} adsorbents, at B97D/6-311G(d,p) level, along with their experimental values

Structure	$\alpha_{calc.}$ (^{3}Å)	$\alpha_{exp.}$ (^{3}Å)[a]	$Gap_{calc.}$ (eV)	$Gap_{exp.}$ (eV)
C_{60}	75.79	76.50 ± 0.80 (ref. 63)	1.66	1.80–1.60 (ref. 56)
Cu_2O	6.68	6.54 (ref. 65)	0.95	2.28 (ref. 57)
ZnO	2.31	2.61 (ref. 64)	0.09	3.37 (ref. 58)
NiO	1.35	2.20 (ref. 64)	0.66	4.00 (ref. 60)
Cu_2O/C_{60}	87.92	—	0.70	—
ZnO/C_{60}	87.35	—	1.09	—
NiO/C_{60}	83.59	—	0.69	—

[a] By empirical findings and Lorentz–Lorenz relation.

Comparing the data in Tables 2 and 8 clearly demonstrate that amount of charge transfer during gas adsorption for the MOx/C_{60} complexes is higher than that for the C_{60}.

Consequently, the high $E_{ads.}$, significant charge transfers during interactions, and notable changes in the enthalpy values, energies of HOMO–LUMO levels and their gaps for the MOx/C_{60} complexes after adsorption of the NO_2 and CO gases indicate strong interactions between these gas molecules and the MOx/C_{60} complexes compared to the weak interactions between them and the fullerene C_{60}.

3.4 Investigation of some reactivity indices in the studied adsorbents

The values of the HOMO–LUMO gap for the fullerene C_{60} (ref. 56) and the Cu_2O,[57] ZnO[58] and NiO[59,60] have been measured during various experiments. These experimental values along with their calculated values in the present study have been given in Table 9.

According to the data in this table, the calculated value of HOMO–LUMO gap for the C_{60} at the theoretical level of B97D/6-311G (d,p) is in good agreement with the experimental value.[56] On the other hand, in the case of the studied MOxs, their calculated gap values are much lower than their experimental values. Despite the remarkable successes of DFT theory in the framework of LDA and GGA approximations, these methods are incapable for prediction some parameters related to the strongly correlated systems.[61,62] The reason is misbehavior of the exchange interactions in these approximations, which do not sufficiently eliminate the electron self-interaction errors, and therefore estimate the energy values of the unoccupied surfaces (LUMO) less than the actual values.[61] Because the intermediate MOxs are the most prominent examples for the strongly correlated systems, the calculated values of their HOMO–LUMO gap using DFT methods are much smaller than the actual values and are not reliable.[61,62]

Since the calculated values of the HOMO–LUMO gap for the MOx molecules are not enough accurate, the study of parameters such as chemical hardness or chemical potential, that are directly related to the HOMO–LUMO gap, are not suitable for checking the stability or reactivity of the studied adsorbent species. The polarizability parameter is one of the reliable indices in computational methods and also determines the chemical hardness of considered systems. The more realistic values of polarizability using empirical findings and Lorentz–Lorenz equation for the C_{60} (ref. 63) and all three MOx molecules (NiO,[64] ZnO[64] and Cu_2O[65]) have been given in Table 9. These values are reasonably consistent with the calculated values here at the studied theoretical level.

According to the obtained data for the polarizability, it can be clearly seen that the adsorbents containing the C_{60} are much softer than the MOx adsorbents, and it is predicted that they exhibit higher conductivity and reactivity. In addition, organic compounds (such as fullerenes) are more readily modified than inorganic materials (including MOxs) and it is expected the MOx/C_{60} complexes would be better detectors or filters for the gas species including CO and NO_2 in comparison with the MOx nanoparticles which have very low selectivity.[66,67]

Interaction between organic–inorganic interfaces alternates electronic states, bond gap and magnetic moment of the substrates. For example, the presence of fullerene in CdSe-C_{60} nanocomposites allows energy levels and band gap of the system to be adjusted by resizing CdSe substrate.[68] In the reaction between the surfaces of C_{60} and tungsten (W), the bond gap can be controlled by selecting the annealing temperature.[69] These are just some example of the bond gap engineering. A selective substrate for adsorption of gases or vapors can be achieved by bond gap engineering in gas adsorbents combined with modified fullerene.[70–74] Other example is modifying polyphenylene oxide membranes (PPO) with fullerene that exhibits a lower gas permeability and enhanced selectivity for gas separation in comparison with the PPO.[70] Combining polystyrene with the fullerene C_{60}, as a hybrid gas separation membrane, leads to a change in the crystallinity, density, and free volume in this membrane. This improve some transport properties which in turn leads to an improvement of the selectivity in the gas separation.[71] Therefore, the modified MOx/C_{60} complexes are expected to show more potent in selectivity of gas adsorptions.

4 Conclusions

Combination of fullerene and MOx, to make composite nanostructures, are interesting not only because they display the individual properties of fullerene and MOx nanoparticles but they may also exhibit synergetic properties that are advantageous for gas sensing applications. The studied MOx molecules, during adsorption on the fullerene C_{60} surface, transfer some electrons to the C_{60}. High adsorption energies, significant changes in the both enthalpy and the HOMO–LUMO values of the fullerene C_{60}, after adsorption of the MOxs, indicate strong interactions in the resulting MOx/C_{60} complexes. According to calculations, the NiO is more stably absorbed on the surface of the C_{60} than the Cu_2O and ZnO.

According to the results, the MOx/C_{60} complexes are much stronger adsorbents than the C_{60} in the gas adsorption. The charge transfers to the NO_2 and CO gas molecules from the MOx/C_{60} complexes are much more significant compared to those from C_{60}. The calculated adsorption energies and the enthalpy changes for adsorption of the studied gas molecules on the MOx/C_{60} complexes are several times larger than those on the C_{60}. These adsorptions on the NiO/C_{60} are stronger than on the other MOx/C_{60} complexes.

According to the obtained data for the polarizability, it can be clearly seen that the adsorbents containing the C_{60} are much softer than the MOx adsorbents, and it is predicted that they exhibit higher conductivity and reactivity. Although the MOx/C_{60} complexes are weaker adsorbents for the NO_2 and CO gases in comparison with the MOxs, but because the organic compounds (such as fullerenes) are more readily modified than inorganic materials (including MOxs), the MOx/C_{60} complexes are more potent in selectivity of adsorption of different gases,

such as CO and NO_2, and they may require lower operating temperatures than the MOxs.

It is expected that combination of the MOxs and the C_{60} three-dimensional system, with the rapid recombination of electron–hole pairs, reduction photo-corrosion processes, also with increase the interaction area surface, would provide ideal gaseous adsorbents with more stability than the MOx adsorbents.
