ABSTRACT: The resource utilization of phosphogypsum (PG) is the key to promote the green development of the phosphorus chemical industry. The natural environment and public safety are significantly threatened by the enormous volume of PG storage. In this study, Ca and S were successfully recovered from the PG via a multistep precipitation in the NaOH-BaCO₃ system. The alkali solution can be recycled five times, with a first recovery ratio of about 97.9%, and the decomposition ratio of PG remained above 70% after five cycles. In addition, the recovery ratios of Ca and S in PG are 99.9 and 82.5%, respectively. The product of $BaSO₄$ can be used as a weighting agent for oil and natural gas drilling mud. The $BaSO₄$ can also be used as wave-absorbing materials, and its reflection loss value reaches 97.8% of the analytical purity BaSO4. This work provides a new idea for the efficient recycling of Ca and S in PG with an outstanding application prospect.

1. INTRODUCTION

The industrial solid-waste phosphogypsum (PG) is produced during the wet process of producing phosphoric acid by decomposing phosphate rock with sulfuric acid.^{[1](#page-7-0)} CaSO₄·*n*H₂O $(n = 0, 1.5, 2)$ is the primary constituent of PG, with F, P, Si, organic material, and some metal impurities like Fe, Mg, and Al.^{[2](#page-7-0)} Some also contain naturally occurring radioactive elements.[3](#page-7-0) The large-scale utilization of PG is seriously restricted by its complex composition. Therefore, it is urgent to study new methods for resource utilization of PG.

The current utilization rate of PG in China is approximately 40%. Massive amounts of PG represent a major threat to the environment.⁴ At present, research on resource utilization of PG primarily focuses on the following aspects: preparing coproduced sulfuric acid cements, 5 preparation of wall materials,^{[6](#page-7-0)} soil conditioner,^{[7](#page-7-0)} and preparation of high-strength $gypsum$, chemical raw materials, modified absorption $m_{\text{interials}}^{(1)}$,^{[10](#page-7-0)} and so on.^{[11](#page-7-0)} In addition, it is used to absorb CO_2 in order to prepare $CaCO_3$.^{[12](#page-7-0)} This approach is beneficial for recovering Ca in PG and absorbing $CO₂$ from the atmosphere, but it overlooks the abundant S. The methods used in many studies are thermal decomposition, thermal reduction decomposition,^{[13](#page-7-0)} dissolution recrystallization,^{[14](#page-7-0)} hydrothermal method,¹⁵ and dehydration rehydration, and so on.^{[16](#page-7-0)} However, with low consumption, high costs, and high energy consumption, the current PG utilization technology is still too immature for industrial use, and the bulk of the methods are still in the laboratory. So, other key technologies to consume PG on a large scale are still needed to further improve the resource utilization of PG.

The precipitation method has the advantages of wide sources of chemicals, low price, simple operation, and reliable treatment. Onoda et al.^{[17](#page-7-0)} selectively precipitated neodymium phosphate from an aqueous solution of iron−neodymium mixture to separate neodymium and iron without the use of high temperature or specialized equipment. Liu et al.^{[18](#page-7-0)} removed and recovered fluoride and phosphate by the stepwise precipitation method, which not only achieved the efficient removal and recovery of F and P but also separated them. Shu et al.¹⁹ used carbonate and struvite precipitation to separate manganese and ammonia nitrogen from the leachate of electrolytic manganese residue. Interestingly, the *K*_{sp} values of CaSO₄, BaCO₃, Ca(OH)₂, CaCO₃, and BaSO₄ are 4.93 \times 10^{-5} ,^{[20](#page-8-0)} 2.58 × 10^{-9} ,^{[21](#page-8-0)} 5.02 × 10^{-6} ,^{[22](#page-8-0)} 2.8 × 10^{-9} ,^{[23](#page-8-0)} and 1.08 × 10[−]10, [20](#page-8-0) respectively. According to the solubility product rule, PG and BaCO₃ can be converted into BaSO₄ and CaCO₃ by multistep precipitation. Therefore, exploring processes for preparing BaSO₄ and CaCO₃ by the precipitation method from PG has become an interesting research topic.

In this study, a multistep precipitation method was proposed to recover Ca and S from PG in the NaOH–BaCO3 system, and Ca and S were fixed as $CaCO₃$ and BaSO₄, respectively.

The filtrate from the final step is rich in OH[−] and can be reused for further leaching. On the basis, a reaction between PG with filtrate recycling is proposed. Meanwhile, the reaction conditions were further optimized using the response surface and single-factor experiments, and the effects of different circumstances on the recovery of Ca and S were investigated. This study can provide a new perspective and method for PG resource development.

2. MATERIALS AND METHODS

2.1. Materials. In this study, pristine PG with tabular morphology from Hubei Province, China was used (Figure 1a), and $CaSO_4.2H_2O$ is the main phase (Figure 1b). The

Figure 1. (a) Scanning electron microscopy (SEM) image of PG and (b) X-ray diffraction (XRD) pattern of PG.

composition of the pristine PG is listed in Table 1 in detail, with the constituents of CaO and SO_3 were major. Prior to the experiment, the PG was crushed to less than 75 *μ*m. NaOH and $BaCO₃$ were of chemical-grade purity and purchased from Aladdin. Deionized water was used in all experiments.

2.2. Methods. The whole reaction element migration and reaction scheme are demonstrated in Figure 2. PG reacts with a certain concentration of NaOH solution to obtain solid 1 (S_1) and liquid 1 (L_1) , and then, L_1 reacts with BaCO₃ to obtain precipitations solid 2 (S_2) and liquid 2 (L_2) . Finally, L_2 reacts with S_1 to obtain precipitations solid 3 (S_3) and liquid 3 (L_3) , and L_3 can be recycled with the newly added PG. The specific experimental steps are as follows:

- 1 Leaching with NaOH: the pretreated PG is added to the NaOH solution according to a certain ingredient ratio $(m_{(NaOH)}:m_{(PG)} = 0.44, 0.46, 0.48, 0.50,$ and 0.52 g/g) and liquid−solid ratio (*m*(H2O):*m*(PG) = 3.0, 3.5, 4.0, 4.5, and 5.0 mL/g). A magnetic stirrer was used to ensure adequate mixing throughout the reaction. The mixture was heated in a water bath to maintain the desired reaction temperature. After leaching for a period of time, the filtrate was collected by vacuum and the residue was dried in an oven at 60 °C for further use. Indicate the solid and liquid as S_1 and L_1 , respectively.
- 2 Preparation of BaSO₄: BaCO₃ (determined from the SO_4^{2-} content in L_1) was added to the L_1 obtained in step 1 under stirring condition, adjusting of different reaction temperatures and reaction times. At the end of

Figure 2. Overall diagrammatic drawing of the phosphogypsum recovery process.

the reaction, the precipitate was then filtered and collected and subsequently dried in an oven at 60 °C. Indicate the solid and liquid as S_2 and L_2 , respectively.

3 Preparation of CaCO₃: a certain content of S_1 was added to the L_2 obtained in step 2 under stirring condition, adjusting of different reaction temperatures and reaction times during the reaction. At the end of the reaction, the subsequent steps are the same as in (2) and indicate the solid and liquid as S_3 and L_3 , respectively. Then, the pretreated PG is added to the L_3 according to the optimal conditions obtained in step 1. The precipitate was then filtered and collected for demonstrating recyclability.

2.3. Analytical Methods. The composition of the sample was detected by X-ray fluorescence (XRF, ARL Perform'X, Thermo Fisher Scientific CDLtd, Switzerland). Samples and precipitates were analyzed by an X-ray diffractometer (D/ MAX-2500, Rigaku, Japan). Microscopic surface morphology and microscale composition analyses were conducted by using SEM (Ultra Plus, Carl Zeiss, Germany) and X-ray energydispersive spectroscopy (EDS, Oxford X-MAX, Carl Zeiss, Germany). Ion chromatography (IC, ICS6000, ThermoFisher Scientific, Germany) and and inductively coupled plasma atomic emission spectrometer (ICP-OES, ICAP6300, Thermo-Fisher Scientific, Britain) were used to measure the ${SO_4}^{2-}$ and $Ca²⁺$ concentrations. Chemical titration was used to assess the amounts of CO_3^2 ⁻ and OH⁻ in accordance with DZ/T 0064.49-2021. Chemical titration was used to assess the amounts of $Ca(OH)_2$ in accordance with GB/T 27815-2011, and the $CaCO₃$ content was assessed. The vector network analyzer (E5071C, Agilent, America) was used to examine the electromagnetic characteristics of the precipitations and determine the reflection loss value.

The recovery of Ca and S was estimated according to the concentrations of ions in the solution before and after the reaction. Thus, the recovery ratio of Ca^{2+} and SO_4^{2-} was determined according to the following eq 1

$$
w_{\text{(Ca}^{2+}/\text{SO}_4^{2-})} = \frac{C_0 - C_1}{C_0} \times 100\% \tag{1}
$$

where C_0 (g/L) is the concentration of calcium and sulfur in the initial PG solution and C_1 (g/L) is the concentration of Ca^{2+} in L_3 and SO_4^{2-} in L_2 .

Table 1. Composition of the Pristine PG (wt %)*^a*

Figure 3. (a) Normal plot of residuals, (b) residuals vs predicted responses, and (c) predicted responses vs the actual values.

The ratio of the primary decomposition ratio to the secondary decomposition ratio is used to estimate the alkaline solution recovery. The decomposition ratio is determined by [eq](#page-1-0) 1, and the only difference is that C_1 (g/L) is the concentration of SO_4^2 ⁻ in L₁. Thus, the recovery ratio of alkaline solution was determined according to eq 2

$$
w_{\text{(alkalinesolution)}} = \frac{w_2}{w_1} \times 100\%
$$
\n⁽²⁾

where w_1 (%) is the primary decomposition ratio of PG, and w_2 (%) is the secondary decomposition ratio of PG.

3. RESULTS AND DISCUSSION

3.1. Optimization of NaOH Decomposes PG by Response Surface Methodology. Since the response

surface method has the advantages of less test time, high precision, and good prediction performance, many researchers have applied this method in various processes and have achieved results.²⁴ The central composite design model offered by Design Expert 10.0 was used in this experiment, and the response surface experiment was set with reaction temperature (*A*), reaction time (*B*), and NaOH concentration (*C*) as independent variables and the PG decomposition ratio as a response value. The quadratic model is selected to fit the obtained data, and the quadratic polynomial regression fitting

equation of the PG decomposition ratio to the coded independent variable is obtained in eq 3

Decomposition ratio =
$$
94.29 + 1.56 \times A + 4.05 \times B
$$

\n $- 3.75 \times C - 0.087 \times AB-$
\n $3.87 \times AC + 11.14 \times BC - 8.31A^2$
\n $- 0.052B^2 - 30.16C^2$ (3)

According to the fitting equation, the responses of test values were anticipated. From Figure 3a,b, it can be seen that the normal probability distribution of the externally studentized residuals is on a straight line, the distribution of the externally studentized residuals and the predicted response values is irregular, and the actual response values of the test and the predicted response values of the model are isotropically distributed along a 45-degree diagonal line, demonstrating the model's ability to accurately and fully identify the response points.²⁵

The ANOVA results showed that the model *F*-value was 65.79, indicating that the prespecified model was reliable (Table 2). The model *P*-values less than 0.0001 confirmed significant model terms. In this optimization case, several model terms such as *B*, *BC*, A^2 , and \overline{C}^2 were in significant form due to their less *P*-values. The values larger than 0.10 means insignificant model terms. In this case, A , AB , and $B²$ were insignificant model terms. The *R*² -value exhibited a measure of how much variability in the observed response values could be expressed by the experimental factors, as well as their interactions, by establishing a relationship between predicated and experimental consequences. R^2 close to one revealed good fitting of experimental data into predicated model equation. The regression model produced higher R^2 up to 0.9834 signifying excellent fitting between model as well as experimental data values.

The reaction surface graph, which can intuitively and vividly show better operating circumstances, is a very important step in the response surface analysis process. [Figure](#page-3-0) 4 shows how temperature, time, NaOH concentration, and their interactions affect the ratio of PG decomposition. The results of response surface plots show that longer reaction times bring more adverse reactions, and the PG decomposition ratio first increases and then declines with the increase of NaOH concentration, a plane with a bent slope is formed. The explanation is that under strong alkali conditions, unnecessary

Figure 4. Response relationship between different factors to the PG decomposition ratio: (a) NaOH concentration and temperature, (b) time and temperature, and (c) NaOH concentration and time.

Figure 5. (a) SO4 $^{2-}$ reaction ratio in different temperatures; (b) XRD pattern of S₂ in different temperatures; (c) SO4 $^{2-}$ reaction ratio in different times; and (d) XRD pattern of S_2 in different times.

NaOH will react with the contamination silicate in PG to produce insoluble substances, such as $CaSiO₃$. The substance will not only consume more NaOH, but it will also increase slag in the reaction cycle, which is not conducive to the subsequent reaction. The increase in temperature will accelerate the reaction ratio. However, the side reaction between an enormous number of impurities and NaOH is an endothermic reaction. The increase in temperature is conducive to the side reaction, resulting in a decrease in the decomposition ratio of PG and an increase in the slag sum. The regression model described above was utilized to optimize the experimental parameters, and the optimal reaction condition was determined as $T = 40$ °C, $t = 30$ min, $m_{(NaOH)}/m_{(PG)} = 0.48:1$, and $m_{(H_2O)}/m_{(PG)} = 4:1$. The leaching ratios of Ca and S were 99.7 and 95.0%, respectively.

3.2. Conversion of BaCO3 into BaSO4 Based on Solubility Product Differences. According to the content of SO_4^2 ⁻ in L₁, the amount of BaCO₃ is calculated. The residual SO_4^2 in the filtrate was used to calculate the reaction ratio. The effects of the reaction temperature and reaction time on the production of $BaSO₄$ were investigated by a singlefactor experiment.

The results obtained are presented in Figure 5. According to Figure 5a, the SO_4^2 ⁻ reaction ratio was 46.6% at 25 °C. The reaction ratio gradually increased with rising temperature. The reaction ratio of SO₄^{2–} peaked at 67.3% at 55 °C. Then, as the temperature continued to rise to 75 °C, the reaction ratio of SO_4^2 ⁻ decreased to 59.6%. This is because, as temperature rises, the movement of molecules intensifies and the possibility of particle collision increases, which facilitates the combination

4667

Figure 6. (a) Ca²⁺ reaction ratio in different amounts of S₁; (b) XRD pattern of S₃ in different amounts of S₁; (c) Ca²⁺ reaction ratio in different temperatures; (d) XRD pattern of S₃ in different temperatures; (e) Ca^{2+} reaction ratio in different times; and (f) XRD pattern of S₃ in different times.

of SO₄^{2–} and Ba²⁺ to form BaSO₄. The reaction ratio of SO₄^{2–} reduces with an increase in temperature because the solubility of Na₂SO₄ increases first before decreasing. Therefore, 55 $^{\circ}$ C was selected as the reaction temperature for producing BaSO₄. [Figure](#page-3-0) 5c shows the impact of reaction time on the reaction ratio of ${SO_4}^{2-}$ at 55 °C. As the reaction time increases, the reaction becomes more and more complete and the SO_4^2 reaction ratio gradually increases. The SO $_4^{2-}$ reaction ratio was 78.3% after 90 min. The SO_4^2 ⁻ reaction ratio did not change much after the reaction time. The XRD pattern of S_2 at different reaction temperatures and times revealed that BaSO4 was the major phase in S_2 , indicating the significant dissolution of CO_3^2 ⁻ in the filtrate and laying the foundation for the subsequent reaction of calcium particles [\(Figure](#page-3-0) 5b−d).

3.3. Conversion of Ca(OH)₂ into CaCO₃ Based on Solubility Product Differences. The CO₃^{2−} content present in the filtrate is used to calculate the Ca^{2+} reaction ratio. Single factor experiments were conducted to investigate the effects of the S_1 amount, reaction temperature, and reaction time on the reaction ratio of Ca^{2+} .

Figure 6a shows that the Ca^{2+} reaction ratio increased gradually with the increasing amount of the $S₁$ additive. The $Ca²⁺$ reaction ratio reached 79.9% when the S1 additive amount was 0.085 g/mL, but it decreased with higher amounts of S_1 . This can mainly be attributed to the production of a supersaturated solution. The solid is difficult to dissolve at high $Ca(OH)_2$ concentrations, and this stage lasts a long time, delaying the ratio of reaction.^{[26](#page-8-0)} Figure 6b displays the XRD patterns of S_3 with varying amounts of the S_1 additive. It can be observed that $CaCO₃$ is the primary phase in $S₃$. When the amount of S_1 is 0.085 g/mL, it can be seen the XRD peak of $Ca(OH)_2$ practically disappears and $CaCO_3$ is the only phase.

Effects of the reaction temperature and time on the amount of Ca²⁺ were discussed in Figure 6, when the amount of S_1 was 0.085 g/mL. At a temperature of 25 $^{\circ}$ C, the Ca²⁺ reaction ratio was 77.6%. As the temperature increased, the ratio gradually decreased until it reached its lowest value at 45 °C, as shown in

Figure 7. (a) XRD pattern of S₁, (b) SEM pattern and matching EDS data for map analysis of S₁, (c) XRD pattern of S₂, (d) SEM pattern and matching EDS data for map analysis of S_2 , (e) XRD pattern of S_3 , and (f) SEM pattern and matching EDS data for map analysis of S_3 .

Figure 8. Reflection loss images of (a) S_2 and (b) analytical purity of BaSO₄.

[Figure](#page-4-0) 6c. The reaction ratio then steadily increased and remained nearly unchanged after 65 °C because the solubility of $Ca(OH)_{2}$ continuously fell and its concentration steadily decreased as the reaction temperature increased. The major phase of the S_3 was $CaCO_3$ under different reaction

Table 4. Analysis Results of Ca^{2+} and SO_4^{2-} Recovery

	theoretical value (g/L)	end of reaction (g/L)	recovery ratio (96)
Ca^{2+}	67.0	11.6×10^{-3}	99.9
SO ₄ ^{2–}	146	25.6	82.5

temperatures [\(Figure](#page-4-0) 6d). [Figure](#page-4-0) 6e illustrates the impact of the reaction time on the reaction ratio. The highest reaction ratio of 89.2% was achieved at 25 °C for a reaction time of 60

Figure 9. (a) Leaching ratio. (b) XRD pattern of the product with various cycle numbers.

min, when the S1 concentration was 0.085 g/mL. Similarly, the major phase observed for S3 at different reaction times was CaCO3, as shown in [Figure](#page-4-0) 6f. CaCO₃ is the sole phase that exists under ideal conditions, and the peak of $Ca(OH)_{2}$ almost completely disappears.

3.4. Precipitation Conversion Caused by Difference in Solubility Product. In order to better explain the reaction process, we analyzed it based on the reaction equilibrium and solubility constant.

NaOH decomposes PG to produce Na_2SO_4 and $\text{Ca}(\text{OH})_2$. The reaction is driven by the difference in solubility between $CaSO₄$ and $Ca(OH)₂$, proceeding toward the production of less soluble $Ca(OH)_2$. In [Figure](#page-5-0) 7a, the main phase of the product is $Ca(OH)_2$. The SEM pattern and matching EDS data for map analysis of the product are demonstrated in [Figure](#page-5-0) 7b. The reaction equation

$$
CaSO_{4}\cdot 2H_{2}O + 2NaOH = Ca(OH)_{2} + Na_{2}CO_{3} + 2H_{2}O
$$
\n(4)

Again, depending on the difference in solubility, $Na₂SO₄$ in L_1 undergoes a precipitation conversion reaction with BaCO₃ to produce $BaSO₄$ [\(Figure](#page-5-0) 7c). The main morphology of the product BaSO₄ is fusiform ([Figure](#page-5-0) 7d), and $Na₂CO₃$ is enriched in L_2 . The reaction equation

$$
Na2SO4 + BaCO3 = BaSO4 + Na2CO3
$$
 (5)

Then, the $Ca(OH)_2$ in S₁ and Na₂CO₃ in L₂ engage in a precipitation conversion reaction to produce $CaCO₃$ due to the difference in solubility, and the OH⁻ is enriched in L_3 . XRD analysis of $CaCO₃$ showed the presence only of calcite polymorph [\(Figure](#page-5-0) 7e). The polymorphic forms of $CaCO₃$ (aragonite and vaterite) were not identified, and the main morphology is spherical [\(Figure](#page-5-0) 7f). The reaction equation

$$
Ca(OH)_2 + Na_2CO_3 = CaCO_3 + 2NaOH
$$
 (6)

3.5. Prospect Analysis of Products Used as Wave-Absorbing Materials. Two precipitations are obtained in the multistep precipitation, and $BaSO_4$ and $CaCO_3$ are the dominant chemical components, respectively. At present, the material containing $BaSO₄$ has a wave absorption property.² Tasnim et al.^{[28](#page-8-0)} developed the high-density shielding materials containing higher percentage $(>80%)$ of BaSO₄ and their gamma-ray attenuation parameters have been investigated. The above research provides a possibility for the preparation of wave absorbances by using S_2 .

The precipitations wave-absorption of S_2 qualities were evaluated. [Figure](#page-5-0) 8a demonstrates the change in reflection loss value with frequency for various thicknesses (*d* = 1, 2, 3, 4, and 5 mm). The material's absorbing ability becomes stronger as the reflection loss value decreases. As the thickness reaches 5 mm, the reflection loss spectrum exhibits two peaks (5.00 and 15.00 GHz). The low-frequency peaks in the two peaks are connected to the displacement of the domain wall, and the high-frequency peaks are connected to the rotation of the magnetic domain, based on the understanding of magnetic physics. As the reflection loss value of the material reaches −10.00 dB, the attenuation of the absorbing material to the electromagnetic wave reaches 90% ^{[29](#page-8-0)} The minimum reflection loss value of S_2 is −10.53 dB. This demonstrates that S_2 precipitates, after further processing, exhibit good absorption characteristics and can be used as a radiation protective material. Furthermore, the reflection loss value of S_2 reaches 97.8% compared to the analytical purity of $BaSO₄$ ([Figure](#page-5-0) 8b).

 $CaCO₃$ is widely used in rubber, building materials, coatings, and other fields because of its unique physical and chemical features.^{[30](#page-8-0)} CaCO₃ is the primary phase of precipitations S_3 , and the purity of the S_3 was measured to be 76.1%. The main elements in S_3 are Ca, Si, Na, and O [\(Table](#page-5-0) 3), which can be further used to prepare ceramics, 31 glass-ceramics, 32 or other construction industry, and further research is still underway.

3.6. Recovery of Ca and S and Alkaline Solution Recycle. The contents of residual Ca^{2+} and SO_4^{2-} in the filtrate after the reaction were measured by ICP and IC. The experimental results are displayed in [Table](#page-5-0) 4. Individually, the recoveries for Ca^{2+} and SO_4^{2-} were 99.9 and 82.5%.

In order to evaluate whether the filtrate could be recovered, we conducted experiments on the recovered filtrate. Figure 9 shows the leaching ratio of SO_4^2 ⁻ and the XRD patterns of the products for different filtrate cycle numbers. As the number of filtrate cycles increased, the leaching ratio of SO_4^2 ⁻ gradually decreased (Figure 9a). The leaching ratio of SO_4^2 ⁻ was 95.0% for the first cycle. After five cycles, the leaching ratio of SO_4^2 was 73.3%, and the alkali recovery ratio reduced from 97.9 to 77.1%. This may occur because the concentration of OH[−] decreased as the cycle number increased. As demonstrated in Figure 9b, the phase of the obtained product was $Ca(OH)_{2}$, and as the cycle number increased, the diffraction peak corresponding to $Ca(OH)_2$ gradually weakened. After five cycles, the diffraction peak corresponding to $CaSO_4·2H_2O$ appeared in the product.

4. CONCLUSIONS

This work successfully realized recycling Ca and S from PG in the NaOH–BaCO₃ system. The leaching ratio of Ca²⁺ and SO4 ²[−] in PG was 99.7 and 95.0%, respectively, under the optimized conditions (*T* = 40 °C, *t* = 30 min, $m_{(N_aOH)}/m_{(PG)}$ =

0.48:1, and $m_{(H_2O)}/m_{(PG)} = 4:1$). The recovery of S was 82.5% at 55 °C with a reaction time of 90 min. The recovery of Ca was 99.9% with the amount of S_1 is 0.085 g/mL, the reaction temperature is 25 \degree C, and a reaction time is 60 min. The product $BaSO₄$ can be used to produce wave-absorbing materials, and its reflection loss value reaches 97.8% of the analytical purity $BaSO₄$. Another product is $CaCO₃$ containing Si, Na, and O, after further treatment, which can be used in building materials industries. The alkali solution can be recycled five times, the first recovery ratio is about 97.9%, and the decomposition ratio of PG remained above 70% after five cycles. We convince that the method for PG utilization may have potential application prospect.
