## ABSTRACT

Liver flukes *Fasciola hepatica*, *Opisthorchis viverrini* and *Clonorchis sinensis* are causing agents of liver and hepatobiliary diseases. A remarkable difference between such worms is the fact that *O. viverrini* and *C. sinensis* are carcinogenic organisms whereas *F. hepatica* is not carcinogenic. The release of secretory factors by carcinogenic flukes seems to contribute to cancer development however if some of these target the host cell nuclei is unknown. We investigated the existence of *O. viverrini* and *C. sinensis* secretory proteins that target the nucleus of host cells and compared these with the corresponding proteins predicted in *F. hepatica*. Here we applied an algorithm composed by *in silico* approaches that screened and analyzed the potential genes predicted from genomes of liver flukes. We found 31 and 22 secretory proteins that target the nucleus of host cells in *O. viverrini* and *C. sinensis*, respectively, and that have no homologs in *F. hepatica*. These polypeptides have enriched the transcription initiation process and nucleic acid binding in *O. viverrini* and *C. sinensis*, respectively. In addition, other 11 secretory proteins of *O. viverrini* and *C. sinensis*, that target the nucleus of host cells, had *F. hepatica* homologs, have enriched RNA processing function. In conclusion, *O. viverrini* and *C. sinensis* have 31 and 22 genes, respectively, that may be involved in their carcinogenic action through a direct targeting on the host cell nuclei.

## 1. Introduction

Liver infections caused by flukes or trematodes, also termed parasitic flatworms, are considered a serious global public health problem with over 60 million people infected around the world and above 10% population at risk of these infections (Fürst et al., 2012a; Prasad et al., 2011). The burden of these infections in the world is widely distributed with high prevalence rates in Asia and South America (Marcos et al., 2007; Parkinson et al., 2007; Machicado et al., 2016) whereas other regions have less prevalence rates (Saijuntha et al., 2019). This demonstrates the widespread distribution of liver flukes throughout the world that leads to huge economic losses in animal husbandry and morbidity in humans.

Among the causative flukes of trematodiasis, *O. viverrini* and *C. sinensis*, two human carcinogens, causes opisthorchiasis and

clonorchiasis, respectively, that affect both the bile ducts and the liver parenchyma (WHO, 2020). About one out of six individuals with opisthorchiasis may develop cholangiocarcinoma (CCA), or cancer of the bile ducts (Haswell-Elkins et al., 1994; Parkin, 2006). Similarly, chronic infection by *C. sinensis* produces liver fibrosis and CCA. The mechanism of carcinogenesis displayed by these worms is multifactorial and it comprises the mechanical irritation of biliary tissue, the chronic tissue inflammation and the toxic action of secreted factors (Buisson, 2007). Interestingly, secreted mitogens such as Ov-GRN-1 by *O. viverrini* stimulate cell proliferation, angiogenesis and wound repair (Smout et al., 2015). To perform these tasks, the secreted proteins should be either recognized by membrane receptors of host cell or enter the cell. Subcellular targeting will depend on the nature of the parasite proteins. Whether some *O. viverrini* or *C. sinensis* proteins target the nucleus of the host cell is unknown.

*Fasciola hepatica* is a fluke that causes an acute liver disease termed fascioliasis with eosinophilic abscesses through the liver parenchyma and a chronic infection in the biliary ducts leading to fibrosis and sometimes cirrhosis (Marcos et al., 2009). Morbidity caused by fascioliasis in children has been associated with malnutrition and anemia (Cabada and White, 2012). On the other hand, the chronic infection in adults may cause significant morbidity including cholangitis, biliary stones, cholecystitis, biliary obstruction, among other complications (Gandhi et al., 2019; Robinson and Dalton, 2009). Last, but not least, the emergent resistance of *Fasciola* to the only active drug in clinical practice, triclabendazole, both in animals and humans has brought major concerns to the veterinary and medical societies (Overend and Bowen, 1995; Brennan et al., 2007; Kelley et al., 2016).

*O. viverrini*, *C. sinensis* and *F. hepatica* are relative organisms with close phylogenetic relationships and phenotypical features (Fürst et al., 2012b). Despite those biological similarities there is a remarkable difference among liver flukes. *O. viverrini* and *C. sinensis* is a causative agent of cancer whereas *F. hepatica* is not reported as such. Hypothetically, different pathogenicity factors and different host response to each liver fluke infection might suggest that *O. viverrini* and *C. sinensis* releases cancer inducer factors whereas *F. hepatica* might not. The transcriptomes of these flukes might provide insights on these questions and establish differences at a genomic and transcriptomic levels that help explain the carcinogenic properties of *O. viverrini* and *C. sinensis*.

During infection, microorganisms release pathogenic factors and other proteins that facilitate the entry and survival of the pathogen agent. Subcellular targeting of pathogenic effectors to different locations within the host cell would be of vital importance for survival of microorganisms (Eickhoff et al., 2007). A major interest is the nuclear targeting because DNA may be damaged by exogenous molecules. Since DNA damage (i.e. point mutations) is associated with cancer there is an increasing interest in recognizing effectors released by infectious agents, particularly bacteria, that target the host nucleus (Xia et al., 2019). Nuclear targeting displays different mechanisms that depend on the proteins size. Small proteins (MW < 40 KDa) can enter the cell nucleus through passive diffusion. In the other hand, larger proteins (MW > 40KDa) are dependent of a nuclear localization signal (NLS) linked to the immature proteins that establish the final protein location (Freitas and Cunha, 2009). This mechanism has been suggested for the nuclear targeting protein urease A (ureA) of *Helicobacter pylori* that has been associated with the bacterial pathogenicity (Lee et al., 2015).

Some bacterial secretory factors that target host cell nucleus have been identified by *in silico* screening of bacterial genomes aimed to find NLSs. For instance, 49 proteins were predicted to have a putative NLS in *H. pylori* which were further localized in the nucleus by experiments in COS-7 cells (Lee et al., 2012). DNA damage promoted by secretory proteins that target the cell nucleus is a plausible mechanism of cell transformation meaning that carcinogenic agents (i.e. bacteria, parasites and virus) would promote cell transformation through a set of nuclear targeting factors (Benamrouz et al., 2012). For instance, a hypothetical relationship between *Mycoplasma* infection and prostate cancer development has been proposed by the finding of 29 bacterial secretory proteins that target the host cell nucleus (Khan et al., 2016a). Similarly, an *in silico* study predicted 47 secretory and nuclear targeting proteins from *C. pneumoniae* that may have the potential to trigger lung cancer through the alteration in replication, transcription, and DNA damage repair mechanisms (Khan et al., 2016b).

In liver flukes, excretory and secretory products (ESPs) of adult worms have been determined by experimental assays (Mulvenna et al., 2010; Robinson et al., 2009; Di Maggio et al., 2016; Zheng et al., 2011). ESPs from liver flukes are composed by enzymes, cytoskeleton proteins, miRNAs and antioxidants and its composition varies with the developmental stage. The subcellular localization of the ES proteins is mostly cytoplasmic, but some factors are predicted nuclear located (Shi et al., 2020). The fact that extracellular vesicles (EVs), produced by liver flukes, contain a major portion of ESPs suggests that exosomes transport factors

that mediate the immune response during the parasite infection (Nawaz et al., 2019). Therefore some nuclear targeting ES proteins released by worms may play a major role in their pathogenesis and further cell transformation by carcinogenic liver flukes. Whether these nuclear ES proteins target or not the host cells is still an open question.

Herein we hypothesize that some ES proteins of both *O. viverrini* and *C. sinensis* target the host nucleus and they are missing in *F. hepatica*. The aim of this study is to predict and compare the nuclear targeting of secretory proteins present in *liver flukes* and to recognize their role within the host cell. Such knowledge will bring insights of unique actions in the host nucleus displayed by factors released by *carcinogenic worms* but unlikely by *F. hepatica* during infection. Future *in vitro* studies of such proteins in *liver flukes* will be needed as well as the determination of their potential effects on the host DNA.

## 2. Materials and methods

### 2.1. Protein database of the parasites genomes

The proteomes deduced from the genomes of *O. viverrini*, *F. hepatica* and *C. sinensis* were downloaded from the WormBase Parasite database version WBPS9 (<https://parasite.wormbase.org/index.html>). WormBase Parasite database encompasses flatworms as well as nematodes, and provides genome sequence, genome browsers, semi-automatic annotation and comparative genomics data for approximately one hundred species (Howe et al., 2016, 2017). The *O. viverrini*'s genome analyzed had the BioProject ID PRJNA222628, assembly OpiViv1.0 deposited in 2014 (Young et al., 2014). The *F. hepatica* genome was under the BioProject ID PRJEB25283 (Cwiklinski et al., 2015a). The *C. sinensis*' genome analyzed here was under the BioProject ID PRJDA72781 deposited in 2013 (Huang et al., 2013).

### 2.2. Prediction of subcellular localization in eukaryotic cells

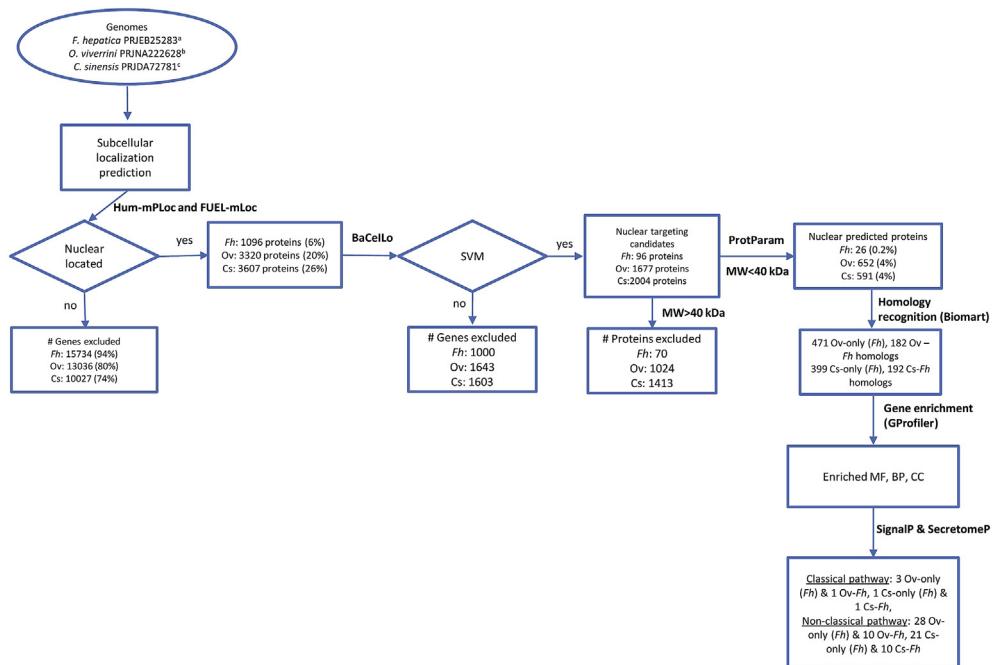

The whole proteins coded by genes have a subcellular localization defined as its final location within a cell. Subcellular localization of the whole genes that compose the genomes of *O. viverrini*, *F. hepatica* and *C. sinensis* was predicted through FUEL-mLoc web-server (<http://bioinfo.eie.polyu.edu.hk/FUEL-mLoc/>). This algorithm uses Feature-Unified prediction and Explanation of multi-Localization of cellular proteins in multiple organisms (Wan et al., 2017). Those nuclear predicted proteins were selected and analyzed by Balanced Subcellular Localization Predictor, BaCeILo (<http://gpcr.biocomp.unibo.it/bacelilo/pred.htm>), a computational tool assists in the prediction of protein subcellular localization including nucleus, cytoplasm, secretory pathway, mitochondrion and chloroplast. BaCeILo is based on different support vector machines organized in a decision tree (Pierleoni et al., 2006). The resulting proteins were named "Nuclear targeting candidates".

### 2.3. Analysis of physicochemical properties of the nuclear targeting proteins

Theoretical isoelectric point (pI) and molecular weight (MW) were obtained through ProtParam (<https://web.expasy.org/protparam/>). This tool provides the physicochemical profile for a given protein deposited in Swiss-Prot or TrEMBL or for a user entered protein sequence (Gasteiger et al., 2005). The amino acid sequences were entered in ProtParam and data was retrieved for each protein considered as nuclear targeting candidates. Only those proteins with MW less than 40 KDa were selected as potential to target the nucleus of host cells. The resulting proteins were named "Nuclear predicted proteins".

### 2.4. Gene ontology and recognition of orthologs

Transcript IDs of *O. viverrini* and *C. sinensis* corresponding to the nuclear predicted proteins with <40 KDa were entered in Biomart available

**Figure 1.** Flowchart of the study. *Fasciola hepatica* (Fh), *Opisthorchis viverrini* (Ov), *Clonorchis sinensis* (Cs). Potential genes predicted from genome: <sup>a</sup> n = 16830 genes, <sup>b</sup> n = 16356 genes, <sup>c</sup> n = 13634 genes. SVM: Support Vector Machine.

in WormBase Parasite Database (<https://parasite.wormbase.org/biomart/martview>) to obtain the gene description, gene ontology, and UNIPROT IDs. In addition, the section Homology implemented in Biomart was used both to identify homologs between *O. viverrini* and *F. hepatica* as well as *C. sinensis* and *F. hepatica*. First, transcript IDs of *O. viverrini* were entered and then the option “Restrict results to genes with orthologues in *F. hepatica*” was activated, to recognize homologs in these species. Then, transcript IDs of *O. viverrini* were entered and the option “Restrict results to genes without orthologues in *F. hepatica*” to recognize the *O. viverrini* exclusive proteins, not present in *F. hepatica*. The same procedure was applied to identify *C. sinensis* homologs in *F. hepatica* by entering the name of such organisms. Homology analysis was conducted considering the available genomes mentioned in 2.1.

## 2.5. In silico secretion analysis

SignalP v 5.0 ([Almagro et al., 2019](#)) and SecretomeP v. 2.0 ([Bendtsen et al., 2004](#)) were used to predict secretory proteins that belong either to the classical or non-classical secretory pathway, respectively. This analysis was done for Ov-only proteins, Cs-only proteins, Ov-Fh homologs and Cs-Fh homologs. Through SignalP, those proteins that had an N-terminal signal peptide (SP) were considered secretory factors. In SecretomeP, those proteins with a NN-value > 0.9 were selected.

## 2.6. Search for genes in available transcriptomes, data from ESPs and extracellular vesicles (EVs) from adult worms

The predicted nuclear ES proteins of *O. viverrini* and *C. sinensis* were searched in data available from their transcriptomes ([Young et al., 2014](#); [Huang et al., 2013](#)) as well as in data from their ESPs ([Mulvenna et al., 2010](#); [Zheng et al., 2011, 2013](#); [Shi et al., 2020](#)) and EVs, these latter described for *O. viverrini* ([Chaiyadet et al., 2015](#)). Data from EVs of *C. sinensis* was not available. Sequences were subjected to either Blastx or Blastp analysis through Blast + against sequences of the available transcriptomes. Those sequences that aligned across >50% of their length and shared more than 40% amino acid identity with p-value < 0.05 were considered positive matches. For ESPs and EVs, the polypeptide IDs were searched for through the supplementary data of publications ([Mulvenna et al., 2010](#); [Zheng et al., 2011, 2013](#); [Shi et al., 2020](#); [Chaiyadet et al., 2015](#)).

## 2.7. Functional enrichment

The set of genes that resulted unique either to *O. viverrini* or to *C. sinensis* that code nuclear predicted factors, were entered in gProfiler ([Reimand et al., 2007](#)) to run an enrichment analysis. The genomes of *O. viverrini* and *C. sinensis*, mentioned in 2.1., were individually selected

**Table 1.** Nuclear predicted proteins of *O. viverrini*, *C. sinensis* and *F. hepatica* that meet the MW criterion and that were predicted secretory proteins.

Gene ontology (GO) obtained through Biomart. Polyptide IDs correspond to the UniProtKB/TrEMBL IDs. The presence and absence of a secretion pathway is denoted with “-” if it is absent and “+” if it is present. References appear in the manuscript.

as the study genomes in gProfiler. Statistical domain scope under the advanced options was set to All known genes/all annotated genes, whereas the Significance threshold was changed to Benjamini-Hochberg FDR and the user threshold set as of 0.05. Graphics and tables were downloaded and further analyzed. The procedure was repeated with both *O. viverrini* genes that had homologs in *F. hepatica* and *C. sinensis* genes that had homologs with *F. hepatica*.

### 3. Results

#### 3.1. Prediction of the subcellular localization and physicochemical properties of nuclear predicted proteins

*F. hepatica* had more potential genes predicted from the genome ( $n = 16830$ ) than *O. viverrini* ( $n = 16356$ ) and *C. sinensis* ( $n = 13634$ ). The predicted genes of these three parasites were not specific-stage genes which means that these can be expressed in any live stage of liver flukes. Next, these genes were analyzed through various computational tools as shown in Figure 1. First, FUEL-mLoc was applied to recognize nuclear targeting candidates. This tool predicts targeting into 22 different sub-cellular locations including nucleus, cytoplasm, extracellular, cell membrane, mitochondrion, cytoskeleton, Golgi-apparatus, endoplasmic-reticulum, chloroplast, vacuole, centrosome, lysosome, cell-wall, endosome, peroxisome, synapse, melanosome, spindle-pole-body, microsome, cianelle, undetermined and unknown locations. A total of 3320 polypeptides of *O. viverrini* and 3607 polypeptides of *C. sinensis* were predicted nuclear located which is higher than the number predicted for *F. hepatica* ( $n = 1096$ ) as shown in Figure 1.

All of these proteins were selected for a second analysis with BaCello, to determine subcellular localizations. As a result, *C. sinensis* contained more nuclear targeting candidates ( $n = 2004$ ) than *O. viverrini* ( $n = 1677$ ) and *F. hepatica* ( $n = 96$ ) (Figure 1).

The whole predicted nuclear targeting candidates were selected for further analysis. MW and pI were computed for each nuclear targeting candidate (Table S1). In this study those proteins with MW  $< 40$  kDa were selected as candidates to target the cell nucleus according to previous work (Khan et al., 2016a). Our results showed that 39% of *O. viverrini* candidates ( $n = 652$ ), as well as 29% of *C. sinensis* candidates ( $n = 591$ ) and 27% of *F. hepatica* candidates ( $n = 26$ ) had MW  $< 40$  kDa (Figure 1, Table 1). Gene annotations were mostly available for *C. sinensis* and *O. viverrini* candidates than *F. hepatica* proteins (Table 1).

#### 3.2. Homology recognition and prediction of secretory proteins

To test our hypothesis, we identified through Biomart those nuclear targeting proteins that were unique either to *O. viverrini* or *C. sinensis* and that had no orthologs in *F. hepatica*. These proteins were named Ov-only (Fh) or Cs-only (Fh) proteins, respectively. By applying this criterion, 471 Ov-only (Fh) and 399 Cs-only (Fh) polypeptides were predicted nuclear targeting proteins (Tables 2 and 3). Also we found that 182 and 192 nuclear predicted proteins present in *O. viverrini* and *C. sinensis* had homologs in *F. hepatica*, here termed Ov-Fh and Cs-Fh homologs, respectively (Tables 4 and 6).

Next we applied *in silico* approaches to determine which nuclear predicted proteins were secretory factors, here termed predicted nuclear ES proteins. In summary, 37 Ov-only proteins (missing both in *C. sinensis* nor *F. hepatica*) and 25 Cs-only proteins (missing both in *O. viverrini* and *F. hepatica*) were identified (Tables 2 and 3). Homologies were further recognized among the predicted nuclear ES proteins of the three liver flukes studied. We found that 11 Ov-Fh homologs, 11 Cs-Fh homologs, 13 Ov-Cs homologs and 15 Cs-Ov homologs were predicted secretory and targeting the cell nucleus (Tables 4 and 5). Most of the nuclear predicted ES proteins were recognized by SecretomeP as secretory proteins by the non-classical secretion pathway compared with the classical secretion pathway (Tables 2, 3, 4, and 5). The Ov-only proteins (missing in *C. sinensis* and *F. hepatica*) that were predicted secretory and nuclear

targeting had an average MW slightly lower (21 kDa) than Ov-Fh homologs (27 kDa) (Tables 2 and 4). The Ov-only secretory and nuclear proteins had slightly higher average pI (average value = 8) than the Ov-Fh homologs (average value = 7) (Tables 2 and 4). The Cs-only nuclear ES proteins (missing in *O. viverrini* and *F. hepatica*) had identical average MW (25 kDa) and pI (value = 8) to the Cs-Fh homologs (Tables 3 and 5). Also some *O. viverrini* proteins had homologs with *C. sinensis*, and vice-versa. Our results showed that the Ov-Cs homologs had a lower average MW (22 kDa) than Cs-Ov homologs (27 kDa) whereas the pI is similar (average value = 8) as shown on Tables 4 and 5. Of interest, no *F. hepatica* nuclear predicted protein was secretory.

### 3.3. Search for predicted nuclear ES proteins from *O. viverrini* and *C. sinensis* in experimental data

The predicted nuclear ES proteins of liver flukes were searched for both in the available transcriptomes and ESPs/EVs data obtained from adult flukes. Of the 37 Ov-only proteins (Table 2), all of these appeared in the available transcriptome whereas one is present in EVs (polypeptide ID A0A074ZQZ9), which is missing in *F. hepatica*, and no protein appeared in ESPs (Table 2). According to the ontology data, A0A074ZQZ9 is a tRNA (adenine(58)-N(1))-methyltransferase non-catalytic subunit TRM6 that is theoretically secreted by the non-classical pathway. Additionally, the whole Cs-only proteins ( $n = 25$ ) appeared in the available transcriptome whereas one Cs-only (Fh), Zinc finger protein 629 (H2KPV8) appeared in ESPs (Table 3).

### 3.3. Gene ontology and enrichment analysis

Gene ontology (GO) was assessed for the 37 Ov-only nuclear predicted ES proteins (Table 2). Ontology was available only for 11 Ov polypeptides including five proteins that were missing in *F. hepatica* (A0A074YXA4, A0A075AIX5, A0A075AJD9, A0A074ZQZ9, and A0A074ZB31). DNA binding and regulation of transcription were the most common MF and BP predicted in Ov-only proteins, respectively. In the other hand, both MF and BP were predicted for most of the Ov-Fh homologs and indicated that DNA/RNA binding and regulation of transcription were the most common MF and BP, respectively (Table 4). These findings showed that GO of the Ov-only nuclear predicted ES proteins and Fh-Ov homologs are similar. The same assessment was done to the 25 Cs-only predicted nuclear ES proteins showing that those polypeptides that are missing in *F. hepatica* have DNA/nucleic acid binding and regulation of transcription as main MF and BP, respectively (Table 3). The Cs-Fh homologs had Zn ion- and DNA-binding as main MFs and transcription regulation as main BP (Table 5).

Next, protein enrichment analysis was carried out on the Ov-only (Fh) proteins and Ov-Fh homologs showing that the transcription initiation factor activity is enriched (GO:0006359, adjusted p-value <0.05) and it involved to the polypeptide A0A075AJD9 as shown on Table 6. A0A075AJD9 is an Ov-only (Fh) predicted TFIIB-type domain-containing protein that has a Zinc finger domain. The transcription initiation factor activity was missing among the Ov-Fh homologs. There was no BP or CC obtained from the enrichment analysis for Ov-only (Fh) proteins. Among the 11 Ov-Fh homologs, the RNA cap binding and nucleic acid binding were two enriched MFs (Table 6). The former comprised the U6 snRNA-associated Sm-like protein LSm1 (A0A074Z2V9) whereas the Nucleic acid binding function comprised two Homeobox domain-containing proteins, as well as a Zinc finger, C2H2 type and the U6 snRNA-associated Sm-like protein LSm1. These functions were missing among the Ov-only proteins. Gene expression and mRNA processing were enriched BPs among the Ov-Fh homologs and these involved proteins such as Homeobox domain-containing protein, Mediator of RNA polymerase II transcription subunit 10, and U6 snRNA-associated Sm-like protein LSm1 (Table 6).

The enrichment analysis was also run with the 25 Cs-only (Fh) genes and Cs-Fh homologs (Table 7). The results showed that the nucleic acid

binding is an enriched MF that comprised six Cs-only (Fh) genes (GO: 0003676, p-value <0.05) including three zinc finger proteins (H2KPV8, H2KQ76 and G7YVI2) as well as a hormone binding factor, histone 3 and Cyclophilin E (Table 7). One of these factors is Zinc finger protein 629 (H2KPV8), a protein that is present in *C. sinensis* but is missing in *F. hepatica*. Nucleic acid binding was an enriched MF in the group of Cs-Fh homologs but it was regulated by different factors from Cs-only proteins. Among Cs-Fh homologs, nucleic acid binding was mediated by up to seven factors including two homeobox proteins (Homeobox protein MSX-2 and Visual system homeobox 1), DNA-directed RNA polymerase I subunit RPA12, Transcription factor SOX1/2/3/14/21, Protein giant, and ETS translocation variant 1/4/5. Cs-Fh homologs had enriched the transcription regulator activity, protein dimerization and heterocyclic compound binding (Table 7). Enriched BPs associated with Cs-Fh homologs include transcription regulation, RNA biosynthesis, and others and these involved proteins such as ETS translocation variant 1/4/5, Protein giant, Homeobox protein MSX-2, among others (Table 7). There was no BP or CC enriched for Cs-only (Fh) genes.

In summary, the transcription activity was a MF strongly associated with at least one Ov-only (Fh) protein whereas such activity is missing among the Ov-Fh homologs (Table 6). RNA processing was a BP enriched in the Ov-Fh homologs but it was missing in the Ov-only proteins (Table 6). At the contrary, Cs-only (Fh) proteins and Cs-Fh homologs had enriched the acid nucleic binding function through different factors that regulate such activity.

## 4. Discussion

In this study we interrogated the entire predicted genes from genomes of *O. viverrini*, *C. sinensis* and *F. hepatica* to look for secretory proteins that target the nuclei of host cells. Our main interest was to identify proteins unique to carcinogenic liver flukes and missing in *F. hepatica*, to learn about their associated functions. We applied both MpLoc and BaCelLo, two *in silico* machines for subcellular localization and recognition of nuclear localization, followed by an additional criterion related to the protein size. Our rationale was that the property of proteins to passively cross into host subcellular compartments is governed by their molecular weight (Tran and Wente, 2006). Therefore, we established that nuclear targeting candidates with molecular weight below 40 kDa were able to passively cross the nucleus, as it was previously described (Khan, 2014). This method has demonstrated to be a suitable tool as an initial exploration for nuclear targeting prediction in *E. coli*, *M. hominis* and *C. pneumoniae* (Khan, 2014; Khan et al., 2016a, 2016b).

As a first and notable finding was the number of genes encoding nuclear predicted proteins of *F. hepatica* that is notably lower than these predicted in *O. viverrini* and *C. sinensis*. According to our results, the carcinogenic helminths have thousands of nuclear predicted proteins whereas *F. hepatica* have only 26. This amount is comparable with the number of nuclear predicted proteins in bacteria, such as *H. pylori* ( $n = 26$ ), *M. hominis* ( $n = 29$ ) and *C. pneumoniae* ( $n = 47$ ) (Lee et al., 2012; Khan et al., 2016a, 2016b).

The transcriptomes of liver flukes have been sequenced and analyzed and the existence of genes encoding peptidases, cathepsins, metabolic enzymes and transporters is particularly relevant in this group of worms (Cwiklinski et al., 2015a; Young et al., 2014; Huang et al., 2013). Although the subcellular localization of proteins may be estimated from the transcriptomes of liver flukes, it is the first time to the best of our knowledge that the secretory proteins that target the nucleus of host cells are identified in these three related flukes through *in silico* approaches. Here by applying a homology search we found that some genes are present in the carcinogenic liver flukes but are missing in *F. hepatica*, here termed Ov-only (Fh) and Cs-only (Fh) genes. We predicted that a total of 471 and 399 nuclear targeting proteins are present only either in *O. viverrini* or *C. sinensis*, respectively, but these are missing in *F. hepatica*. Such polypeptides, that are not specific-stage factors, may be associated with some unique features shown in infection by *O. viverrini* and

**Table 3.** Proteins identified from the *Clonorchis sinensis* transcriptome that were nuclear predicted ES polypeptides and that were unique to *C. sinensis* (Cs-only).

Gene ontology (GO) obtained through Biomart, MF is Molecular Function, BP is Biological Process and CC is Cellular Component. Polypeptide IDs correspond to the UniProtKB/TrEMBL IDs. The presence and absence of a secretion pathway is denoted with “-” if it is absent and “+” if it is present. References appear in the manuscript.

**Table 4.** Proteins identified from the *Opisthorchis viverrini* transcriptome that had homologs in *F. hepatica* (Ov-Fh) or *C. sinensis* (Ov-Cs).

Gene ontology (GO) obtained through Biomart, MF is Molecular Function, BP is Biological Process and CC is Cellular Component. Polypeptide IDs correspond to the UniProtKB/TrEMBL IDs. The presence and absence of a secretion pathway is denoted with “-” if it is absent and “+” if it is present. References appear in the manuscript.

**Table 6.** Enrichment analysis obtained for the Ov-only (Fh) nuclear predicted ES proteins and Ov-Fh homologs.

*C. sinensis*. In addition, we predicted that carcinogenic liver flukes have homologs in *F. hepatica*, here termed Ov-Fh and Cs-Fh homologs. We found that 182 and 192 nuclear predicted proteins of *O. viverrini* and *C. sinensis*, respectively, had homologs in *F. hepatica*. Those factors may be associated with common features of the pathogenesis of liver flukes infection.

Part of the transcriptome of liver flukes is composed by genes encoding excretory-secretory (ES) proteins. ESPs from liver flukes contain ES proteins that are a group of polypeptides that are excreted to the extracellular medium where they mediate host-pathogen interactions (Suttiprapa et al., 2018). The secretomes of liver flukes have been previously predicted from the corresponding transcriptomes and most recently determined by experimental techniques. The available secretomes varies across the worms where *O. viverrini* has the biggest secretomes ( $n = 300$ ) followed by *F. hepatica* ( $n = 202$ ) and *C. sinensis* ( $n = 175$ ) (Mulvenna et al., 2010; Di Maggio et al., 2016; Shi et al., 2020). Given that we aimed to predict the secretory proteins that target the nuclei of host cells, the whole nuclear predicted proteins were tested to identify which ones are secreted to the extracellular environment. We applied two approaches including SignalP v 5.0 (Almagro et al., 2019) and SecretomeP v. 2.0 (Bendtsen et al., 2004) which were previously utilized to predict secretory proteins in *Toxoplasma gondii* (Syn et al., 2018). Our results showed the existence of 31 Ov-only (Fh) proteins that have the transcription initiation activity enriched, involving a predicted TFIIB-type domain-containing protein (A0A075AJD9). Zinc finger TFIIB-type proteins assists the RNA polymerase II in the promoter recognition during the transcription. TFIIB-type domain-containing protein from *O. viverrini* is predicted secretory and it targets the host cell nucleus which suggests a relevant strategy of this fluke to interfere with the normal transcription of the host cell. Eukaryotic RNA polymerases are highly conserved and have identical substrates. Therefore a competitive mechanism between the parasites' and human's TFIIB-type domain-containing protein may lead to abnormal transcription (Papapremarsi et al., 2015; Gasser et al., 2017). Given that the polypeptide A0A075AJD9 had no homologs in *F. hepatica* and it was predicted to be secretory and nuclear targeted, we hypothesize that such protein may be involved in the carcinogenic mechanism displayed by *O. viverrini*. However the polypeptide A0A075AJD9 is missing in the available data from the ESPs and EV cargo (Mulvenna et al., 2010; Chaiyadet et al., 2015). Most proteins contained within *O. viverrini* ESPs are associated with enzyme activity and cytoskeleton with less frequency of nuclear proteins (Mulvenna et al., 2010). According to our results, the existence of the TFIIB-type domain-containing protein and its hypothetical role in the opisthorchiasis and cancer development should be further studied. In addition, we found that the polypeptide A0A074ZQZ9, an Ov-only (Fh) found in EVs, is one out of the 108 proteins contained in *O. viverrini* EVs that were demonstrated to promote cell transformation (Chaiyadet et al., 2015). This latter has been mostly associated with the action of granulin and thioredoxin, both present in ESPs, which induced proliferation of host cells by *in vitro* assays (Mulvenna et al., 2010, Chaiyadet et al., 2015). The involvement of a nuclear targeting proteins has not been investigated but our results suggests that tRNA (adenine(58)-N(1))-methyltransferase non-catalytic subunit TRM6 (A0A074ZQZ9) may have an effect on the tRNA methylation of host cells. tRNA methylation and its role in infection by liver flukes is currently an unknown topic.

On the other hand, we found that *C. sinensis* has 22 nuclear predicted ES genes that are missing in *F. hepatica* (Cs-only proteins). Such genes are transcribed and one gene encoding Zinc finger protein 629 is among the ESPs previously characterized in *C. sinensis* (Zheng et al., 2011, 2013; Shi et al., 2020). The role of ESPs in the pathogenesis of clonorchiasis is still unclear but some antigenic factors such as Cs-FBPase, CsMAP-2 and CsAP have been characterized (Zheng et al., 2011, 2013). Zinc finger protein 629 secreted by *C. sinensis* (and missing in *F. hepatica*) has not a demonstrated function but its human homolog Zinc finger protein 423 is an oncogene that contributes to the development of CCA (Chaiprasert

et al., 2019). The function of Zinc finger protein 629 needs to be further investigated.

The finding that 11 polypeptides either in *O. viverrini* or *C. sinensis* are nuclear predicted ES and have homologs in *F. hepatica* (Ov-Fh or Cs-Fh homologs) shows that these phylogenetically related organisms display equivalent mechanisms to manipulate essential activities in the host nucleus. According to the enrichment analysis of Ov-Fh homologs, those common polypeptides are involved in RNA processing and spliceosome function. Consequently, the mRNA maturation in the host cells may be disrupted by the presence of exogenous parasites factors released during the infection by *O. viverrini* and *F. hepatica*. According to our results on Cs-Fh homologs, various activities including heterocyclic compound binding, transcription regulator activity and DNA binding are commonly present in *C. sinensis* and *F. hepatica*. Given that such factors were found in both flukes, these proteins are not expected to be associated with *O. viverrini/C. sinensis* tumorigenesis.

In our study *F. hepatica* had no predicted nuclear ES protein which constitutes a major difference with the carcinogenic liver flukes. ES proteins of *F. hepatica* mainly include proteases, proteases inhibitors and detoxifying enzymes but nuclear proteins have not been described (Di Maggio et al., 2016). A group of ES proteins of *F. hepatica* promote the production of cytokines by the host such as IL2, IL-7 and IFN- $\gamma$  that participate in modulating host immune response (Liu et al., 2017). Again, the existence of nuclear targeting within ES proteins of *F. hepatica* has not been previously investigated but our results suggest that such a type of proteins is lacking in the *F. hepatica* proteome.

The ES proteins have been characterized for liver flukes and these vary across worms. For instance, ES proteins of *O. viverrini* include peptidases, heat shock proteins and superoxide dismutase whereas lipid-binding and -transport factors, cysteine-type peptidase and peptidase inhibitor have been characterized in *C. sinensis* (Young et al., 2014; Huang et al., 2013). ES proteins from *F. hepatica* mainly include peptidases and cytokines, these latter related to evasion of the host immune response (Cwiklinski et al., 2015a; Liu et al., 2017). Existing data of ESPs is mostly related to non-nuclear factors. However our study predicted that a group of ES proteins from liver flukes may target the host cell nuclei. These proteins should be delivered to host cells through specialized delivery mechanisms such as exosomes or EVs which are vehicles for worms ES proteins transport to host cells (Nawaz et al., 2019). The cargo of EVs from *F. hepatica* and *O. viverrini* have been studied through proteomics approaches and the existence of multiple secretory products have been demonstrated (Cwiklinski et al., 2015b; Chaiyadet et al., 2015; Zakeri et al., 2018). There are differences between the cargo and effect mediated by EVs from *O. viverrini* and *F. hepatica*. Released products from EVs of *O. viverrini* trigger gene expression of cancer related genes and wound healing process genes and further lead to develop a tumorigenic phenotype in human cholangiocytes (Chaiyadet et al., 2015). On the other hand, EVs secreted from *F. hepatica* act not only as immune modulators but also are able to sequestrate triclabendazole from the culture media (Marcilla et al., 2012; de la Torre-Escudero and Robinson, 2017; Murphy et al., 2020; Davis et al., 2020). By applying *in silico* approaches we identified one polypeptide (A0A074ZQZ9) present in EVs of *O. viverrini* and predicted other 36 that could be found either in ESPs or EVs. Given that secretion and cargo of EVs depends both on biological stage of parasites and on the technique applied, the existence of the nuclear ES proteins here predicted is plausible.

Pathogens that cause cancer are not considered promoters due to its ability to stimulate cell proliferation. This action is performed by some unique factors that interact with host cell proteins, both in cytoplasm and nucleus, thus displaying a direct effect on cell cycle and survival. Of particular interest are those proteins released by infectious agents that cross the nuclear membrane and can interact with nuclear factors and DNA. Those elements may virtually hijack the host cell cycle by controlling critical processes such as cell cycle, apoptosis, survival and response to DNA damage. Our study predicted that *O. viverrini*, *C. sinensis* and *F. hepatica* have secretory DNA- and RNA-binding proteins such as

**Table 7.** Enrichment analysis obtained for the Cs-only (Fh) nuclear predicted ES proteins and Cs-Fh homologs.

| Cs-Fh homologs |                |  | MF                   | Cs-only proteins                          |                |  |            |

Enrichment analysis done by Gprofiler. MF is Molecular function; BP is Biological process and CC is Cellular component.

Homeobox domain-containing proteins, Zinc finger domain proteins, and Cyclophilin E. Similar findings have been reported in bacteria such as *M. hominis* and *C. pneumoniae*, where secretory DNA-binding proteins have been predicted and suggested to have a role in carcinogenesis (Khan et al., 2016a; Alshamsan et al., 2017). In contrast, our findings show that secretory DNA-binding proteins are present in *O. viverrini*, *C. sinensis* and *F. hepatica* suggesting that it is unlikely the involvement of such proteins in liver fluke-induced carcinogenesis but these may contribute to liver fluke pathogenesis. Actually, cell transformation displayed by *O. viverrini* infection is not only associated with chronic inflammation and proliferation secretory factors that promote cell growth but also with DNA damage such as adducts (Brindley et al., 2015). Other proteins expressed by *O. viverrini* may be able to manipulate some biological process of the host cells by altering certain pathways and molecules both in the membrane and cytoplasm. For instance, thioredoxin, a component of ESP, is a growth factor and apoptosis inhibitor and it might contribute to carcinogenesis (Young et al., 2014; Shi et al., 2020). Similarly, the genesis of *C. sinensis*-induced CCA is also a complex process where certain ES proteins such as cystatin and Oxidoreductase-peroxiredoxin and carbonyl reductase 1 (CBR1) are likely implicated in (Shi et al., 2020). Whether some RNA- and DNA-binding proteins secreted by liver flukes contribute with carcinogenesis or other infection-related features remains unclear.

In summary, we predicted nuclear ESPs of liver flukes by applying an algorithm that is not dependent on presence of NLS which is more suitable given that only 30% of nuclear targeting proteins has NLS (Cokol et al., 2000). The TFIIB-type domain-containing protein of *O. viverrini* and Zinc finger protein 629 of *C. sinensis* may disrupt either replication or transcription process, respectively, in host cells. Further studies are needed to demonstrate whether the predicted polypeptides present in carcinogenic liver flukes participate in cell tumorigenesis.

## Declarations

### Author contribution statement

Claudia Machicado: Conceived and designed the experiments; Performed the experiments; Analyzed and interpreted the data; Contributed reagents, materials, analysis tools or data; Wrote the paper.

Maria Pia Soto: Performed the experiments; Analyzed and interpreted the data; Wrote the paper.

Luis Felipe La Chira, Joel Torres, Carlos Mendoza: Performed the experiments; Analyzed and interpreted the data.

Luis A. Marcos: Conceived and designed the experiments; Analyzed and interpreted the data; Contributed reagents, materials, analysis tools or data; Wrote the paper.

### Funding statement

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

### Data availability statement

Data included in article/supplementary material/referenced in article.

### Declaration of interests statement

The authors declare no conflict of interest.

### Additional information

Supplementary content related to this article has been published online at <https://doi.org/10.1016/j.heliyon.2021.e07204>.
