Mechanisms underlying the beneficial effects of Kaiyu Granule for depression

Xi Jin, Yidan Zhang, Qiaoying Li, Jianjun Zhao

Department of Neurology, Hospital Affiliated to Changchun University of Chinese Medicine, Changchun 130021, Jilin Province, China

Abstract

The proprietary Chinese medicine preparation *Kaiyu Granule* is made of *bupleurum*, *nutgrass galingale rhizome*, *szechwan lovage rhizome*, *turmeric root tuber*, *white peony alba*, *cape jasmine fruit*, *fried semen ziziphi jujubae*, and *prepared liquorice root*. It is a common recipe for the clinical treatment of depression in China. In this study, after 21 days of unpredictable stress exposure, Wistar rats exhibited similar behavioral changes to patients with depression. Moreover, G-protein-coupled inwardly rectifying K⁺ channel 1 mRNA and protein expression were significantly reduced in rat hippocampal CA1 and CA3 regions. However, G-protein-coupled inwardly rectifying K⁺ channel 1 mRNA, protein expression, and rat behavior were clearly better after administration of 12, 8, or 4 g/kg of *Kaiyu Granule* when depression model rats underwent stress. 12 g/kg of *Kaiyu Granule* had the most obvious effects on the increased expression of G-protein-coupled inwardly rectifying K⁺ channel 1 mRNA and protein in rat hippocampal CA1 and CA3 regions. These results suggested that *Kaiyu Granule* improved depression by affecting G-protein-coupled inwardly rectifying K⁺ channel 1 expression in the rat hippocampus.

INTRODUCTION

Chaihu Shugan Powder is a representative recipe for dispersing depressed liver-energy and regulating vital energy in Chinese medicine. Zhu and colleagues^[1] confirmed that *Chaihu Shugan Powder* diminished P-endorphin levels in rat plasma and hypothalamus and indicated that *Chaihu Shugan Powder* regulated hypothalamic-pituitary-adrenal axis in rat models of chronic restraint stress. Xiong and Zhu^[2] verified that *Chaihu Shugan Powder* partially antagonized stress-induced slow increases in body weight, elevated adrenocorticotrophic hor-

mone levels, and increased sucrose water intake in stressed rats, indicating that *Chaihu Shugan Powder* adjusts disordered function in rat models of chronic restraint stress. However, previous studies mainly focused on the effects of Chinese drugs on mitters (serotonin, noradrenalin, dopamine and acetylcholine) in animal models of depression, and have not studied tide protein expression levels in the nerve conduction pathway. *Kaiyu Granule* is a recipe after addition and subtraction of *Chaihu Shugan Powder*, prepared by a Hospital Affiliated to Changchun University of Chinese Medicine, China. Nevertheless, the mechanism of action of *Chaihu Shugan*

Acknowledgments: We are very grateful to Sun B from College of Pharmacy of Jilin University in China for help in conducting immunohistochemistry and *in situ* hybridization, providing advice on technique for data collection, and assisting with the statistical analyses.

Funding: This study was supported by the New Drug Development Special-Purpose Foundation of State Administration of Traditional Chinese Medicine, No. 2005 DIX027A.

Author contributions: Jin X summarized and integrated the data and wrote the manuscript. Zhao JJ obtained the funding, participated in the study concept and design, and revised the manuscript. Zhang YD and Li QY were in charge of raising the rats, model induction, and behavioral experiments. All authors approved the final version of the paper.

Conflicts of interest: None declared.

Ethical approval: This study was approved by the Animal Ethics Committee, College of Pharmacy of Jilin University in China.

Author statements: The manuscript is original, has not been submitted to and is not under consideration by another publication, has not been previously published in any language or any form, including electronic, and contains no disclosure of confidential information or authorship/patent application/funding source disputations.

Powder on depression, especially effects on depression-related protein expression levels remain unclear.

The G-protein-coupled inwardly rectifying K⁺ channel (GIRK) is a member of inwardly rectifying K⁺ channel family. It can be directly activated by G-protein β- and γ-subunits, and it regulates presynaptic membrane neurotransmitter release and neuronal excitability. A previous study verified that GIRK directly coupled to many neurotransmitters and neuropeptide receptors, and is a direct effector between the heart and many neurotransmitters^[3]. GIRK is a member of a seven member subfamily of inwardly rectifying K⁺ channel and is composed of five subunits (*i.e.*, GIRK 1–5). Of these subunits, GIRK1 protein is expressed in hippocampal CA1, CA2 and CA3. GIRK exists as a tetramer. At present, *in situ* hybridization results show that GIRK is extensively distributed in various tissues, couples to various receptors in the central nervous system, and play important roles in maintaining resting potentials and slow postsynaptic inhibition^[4]. A study of G-protein-coupled ion channels has been performed on the acetylcholine potassium channel, which has been shown to be constructed by GIRK 1–4^[5]. Acetylcholine-induced GIRK opening and K⁺ efflux through the G protein induced hyperpolarization. Another study found that each subunit of GIRK1–3 was widely distributed in the brain, such as in the hippocampus, neocortex, olfactory system, diencephalon, and cerebellum^[6]. GIRK4 is mainly distributed to the cerebellar granular cell layer, superior colliculus, lateral septal nuclei, and hippocampal CA3 pyramidal neurons^[7]. Numerous inhibitory neurotransmitters act on their corresponding receptors and then activate GIRK by activating the pertussis toxin-sensitive G protein. GIRK suppresses neuronal excitability by producing slow, inhibitory postsynaptic potentials GIRK regulates neurotransmitter release *via* presynaptic inhibition in the brain. GIRK1 protein in the paraventricular hypothalamic nucleus exists presynaptically but not postsynaptically. Neurons projecting to the paraventricular nucleus are located in several nerve nuclei (such as the nucleus raphe dorsalis and parabrachial nuclei) of the hypothalamus, limbic system, and brain stem^[8].

In situ hybridization results have confirmed that GIRK1 mRNA exists in these neurons, and these neurons contain dopamine, noradrenalin, and neuropeptide. Dopamine, noradrenalin, and neuropeptide receptor have been shown to couple to GIRK in neurons and heterogeneous cells^[9]. In the hippocampal CA1 region, GIRK is connected to excitatory synapses but not to inhibitory synapse, indicating that these channels regulate excitatory synapse-mediated signal afference^[10]. When noradrenergic neurons are in a persistent depolarized excitatory state, GIRKs are in a closed inhibitory state for a long time, and GIRK density on the cell membrane can decrease. This can result in GIRK1 mRNA expression in the hippocampus and parietal cortex that is noticeably lower in depression model subjects compared to controls^[11]. *In situ* hybridization results demonstrate that GIRK1 mRNA expression is lower in the brain of depression model rats. However, GIRK reduced the frequency peak potentials of neurons, produces slow inhibitory postsynaptic potentials, exerts postsynaptic inhibitory effects, and finally suppresses neuronal excitability^[12]. Therefore, GIRK1 mainly exerts postsynaptic inhibitory effects in neurons that can release inhibitory neurotransmitters, such as GABAergic neurons. Reduced GIRK1 expression leads to increased inhibitory effects of GABAergic neurons, possibly suppressing the excitability of aminergic neurons, and providing a biochemical basis for the onset of depression^[13].

In this study, we sought to establish models of depression using classical chronic stress and isolation methods, which are different from pharmacological models and models of olfactory tubercle resection. We analyzed the effects of *Kaiyu* Granule on GIRK1 protein expression in the hippocampal CA1 and CA3 regions of depression model rats using *in situ* hybridization, which has been rarely used previously to study traditional Chinese medicine. We determined the mechanisms of action of *Kaiyu* Granule for the treatment of depression at the molecular level in the neuroendocrine system.

RESULTS

Quantitative analysis of experimental animals

A total of 72 rats were equally and randomly assigned to six groups: normal, model, fluoxetine, low-, moderate- and high-dose *Kaiyu* Granule groups. Models of depression were established using chronic stress in the latter five groups. The rats in the high-, moderate-, and low-dose *Kaiyu* Granule groups were intragastrically administered 12, 8 or 4 g/kg *Kaiyu* Granule. The rats in the fluoxetine group were intragastrically administered fluoxetine hydrochloride capsules. All rats were included in the final analysis.

Kaiyu Granule improved the behavioral performance of depression model rats

Body weight, sucrose water consumption, locomotor activity, and rearing activity significantly increased in depression rats at 22 days of the experiment (at 1 day after drug administration) in the *Kaiyu* Granule groups compared to those in the model group ($P < 0.01$, $P < 0.05$). Moreover, no significant difference in behavior was detected between the *Kaiyu* Granule groups and the fluoxetine group ($P > 0.05$; Tables 1, 2).

Kaiyu Granule increased GIRK1 expression in the

hippocampal CA1 and CA3 regions of depression model rats

GIRK1 expression increased in the hippocampal CA1 and CA3 regions in depression model rats as compared with the normal group. At 21 days after drug administration, no significant alteration in GIRK1 expression was detected in the low-dose *Kaiyu* Granule group ($P > 0.05$), but GIRK1 expression significantly increased in the moderate- and high-dose *Kaiyu* Granule groups and fluoxetine group ($P < 0.05$, $P < 0.01$). It is worthwhile to note that GIRK1 expression in the hippocampal CA1 and CA3 regions was similar in the moderate- and high-dose *Kaiyu* Granule groups and fluoxetine group ($P > 0.05$; Figure 1, Table 3).

Kaiyu Granule increased GIRK1 mRNA expression in hippocampal CA1 and CA3 regions of depression model rats

GIRK1 mRNA expression increased in the hippocampal CA1 and CA3 regions of depression model rats as compared with the normal group. At 21 days after drug administration, GIRK1 mRNA expression significantly increased in various *Kaiyu* Granule groups and the fluoxetine group ($P < 0.05$, $P < 0.01$). It is worthwhile to note that GIRK1 mRNA expression in the hippocampal CA1 and CA3 regions of depression rats was similar between the high-dose *Kaiyu* Granule and fluoxetine groups ($P > 0.05$; Figure 2, Table 4).

Table 1 Effects of *Kaiyu* Granule on body weight (g) and sucrose water consumption (mL) in depression model rats

Group	Dose (g/kg)	Body weight (g)		Sucrose water consumption (mL)	
		Pre-experiment	Day 22 post-experiment	Pre-experiment	Day 22 post-experiment

Data are expressed as the mean ± SD. Each group contained 12 rats. Intergroup differences were compared with one-way analysis of variance. Paired comparisons were performed using two-sample *t*-tests. ^a $P < 0.01$, vs. normal group; ^b $P < 0.01$, ^c $P < 0.05$, vs. model group.

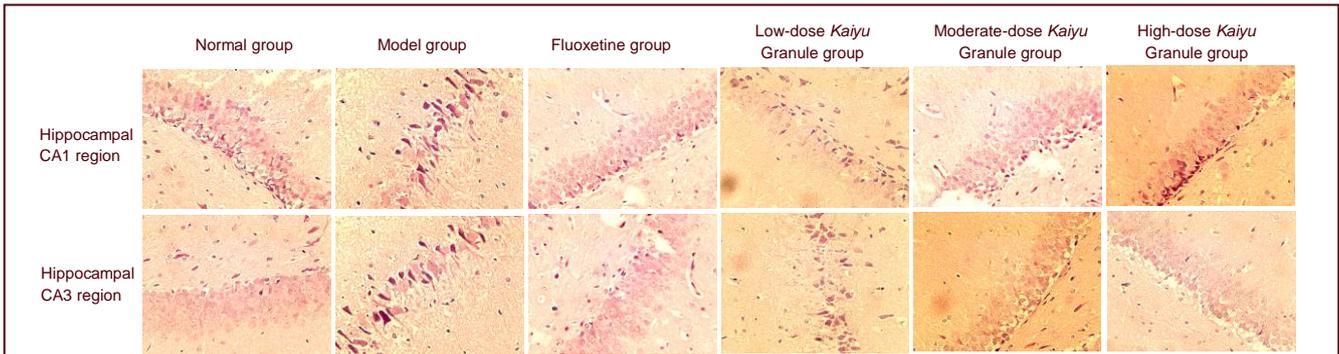

Figure 1 GIRK1 expression in the rat hippocampal CA1 and CA3 regions (immunohistochemistry, × 40).

Moderate- and high-dose *Kaiyu* Granule evidently increased GIRK1 expression in the hippocampal CA1 and CA3 regions of depression model rats, and their effects were similar to those of fluoxetine. GIRK1-positive expression was brownish red color. GIRK: G-protein-coupled inwardly rectifying K⁺ channel.

Table 3 Effects of *Kaiyu* Granule on GIRK1 expression (absorbance) in hippocampal CA1 and CA3 regions of depression model rats

Group	Dose	Hippocampal CA1 region	Hippocampal CA3 region
Normal	—	211.2±4.2	205.2±5.6
Model	—	185.8±8.8 ^a	182.3±1.6 ^a
Fluoxetine	0.02	205.9±3.9 ^a	201.6±1.2 ^a
<i>Kaiyu</i> Granule			
Low-dose	4	186.2±3.2 ^c	184.8±4.2 ^c
Moderate-dose	8	191.9±5.2 ^b	190.0±11.8 ^b
High-dose	12	200.6±7.6 ^a	198.2±13.9 ^a

Data are expressed as mean ± SD. Each group contained 12 rats. Intergroup differences were compared with one-way analysis of variance. Paired comparisons were performed using two-sample *t*-tests. ^a*P* < 0.01, vs. normal group; ^b*P* < 0.05, ^c*P* < 0.01, vs. model group. GIRK: G-protein-coupled inwardly rectifying K⁺ channel.

high-dose *Kaiyu* Granule and fluoxetine groups compared to the untreated depression model group. GIRK1 expression in the hippocampal CA1 region was also high in the low- and moderate-dose *Kaiyu* Granule groups, but apparently reduced in the model group. GIRK1 expression in the hippocampal CA3 region was also evidently increased in the high- and moderate-dose *Kaiyu* Granule groups and fluoxetine group. GIRK1 expression in the hippocampal CA3 region was also high in the low-dose *Kaiyu* Granule group, but obviously diminished in the model group. *Kaiyu* Granule obviously reduced the decrease in body weight in depression model rats and increased sucrose water consumption, which suggested that *Kaiyu* Granule improved their behavior, increased locomotor activity and rearing activity, and improved depression symptoms. Increased GIRK1 mRNA expression reduced postsynaptic inhibitory effects, increased neuronal excitability, diminished the number of neurons that could release inhibitory neurotransmitters such as GABAergic neurons, and decreased postsynaptic inhibitory effects.

DISCUSSION

This study demonstrated that GIRK1 expression in the hippocampal CA1 region was significantly higher in the

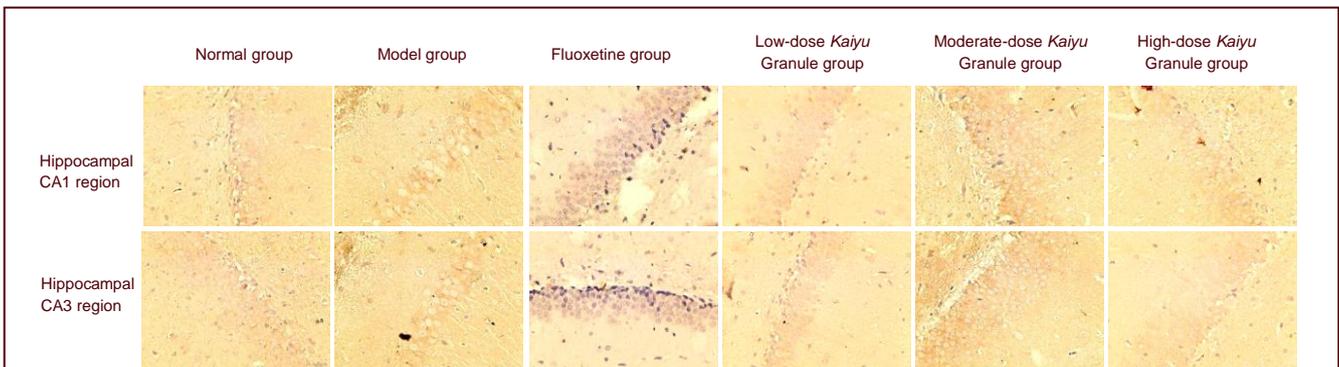

Figure 2 GIRK1 mRNA expression in the rat hippocampal CA1 and CA3 regions (*in situ* hybridization, × 40).

Various doses of *Kaiyu* Granule evidently increased GIRK1 mRNA expression in the hippocampal CA1 and CA3 regions of depression model rats, and their effects were similar to those of fluoxetine. GIRK1 mRNA-positive expression was brownish red color. GIRK: G-protein-coupled inwardly rectifying K⁺ channel.

Table 4 Effects of *Kaiyu* Granule on GIRK1 mRNA expression (gray scale) in the hippocampal CA1 and CA3 regions of depression model rats

Group	Dose	Hippocampal CA1 region	Hippocampal CA3 region
Normal	—	145.3±10.8 ^a	140.0±13.2 ^a
Model	—	105.2±1.4	114.5±3.3
Fluoxetine	0.02	150.9±5.9 ^a	146.0±10.0 ^a
<i>Kaiyu</i> Granule			
Low-dose	4	137.0±19.7 ^{ab}	125.2±16.7 ^{ab}
Moderate-dose	8	138.8±10.3 ^{ab}	132.0±7.4 ^{ab}
High-dose	12	150.7±15.2 ^a	143.2±13.9 ^a

Data are expressed as mean ± SD. Each group contained 12 rats. Intergroup differences were compared with one-way analysis of variance. Paired comparisons were performed using two-sample *t*-tests. ^a*P* < 0.01, ^b*P* < 0.05, vs. model group. GIRK: G-protein-coupled inwardly rectifying K⁺ channel.

Increased GIRK1 expression reduced the inhibitory effects of GABAergic neurons and possibly increased monoaminergic neuronal excitability^[14] decreased depression-like symptoms. In summary, *Kaiyu* Granule could increase GIRK1 expression in hippocampal CA1 and CA3 regions of depression rats, indirectly increase the secretion of monoamine neurotransmitters, and finally reduce depression-like symptoms.

MATERIALS AND METHODS

Design

A randomized controlled animal study.

Time and setting

Experiments were performed in the College of Pharmacy, Jilin University, China, from June 2006 to March 2007.

Materials

Animals

A total of 72 clean adult male Wistar rats aged 2 months and weighing 180–220 g were provided by Changchun Gaixin Animal Center, China, animal license No. SCXK-(Ji) 2007-0003. Animals were allowed free access to food and water (except during fasting diet and water deprivation stress). They were housed at 18–22°C (except during hot and cold stress) and at a humidity of 60–70%. The protocols were conducted in accordance with the *Guidance Suggestions for the Care and Use of Laboratory Animals*, formulated by the Ministry of Science and Technology of China^[15].

Drugs

Kaiyu Granule was provided by Department of Pharmacy, Changchun University of Chinese Medicine, China.

Kaiyu Granule (nosocomial preparation) was made of *bupleurum*, *nutgrass galingale rhizome*, *szechwan lovage rhizome*, *turmeric root tuber*, *white peony alba*, *cape jasmine fruit*, *fried semen ziziphi jujubae*, and *prepared liquorice root*. All materials were decocted three times with an eight-times volume of distilled water, with the first decoction for 2 hours, second decoction for 2 hours, and third decoction for 1 hour. Decoction solutions were mixed and filtered. Filtrate was condensed to clear paste, which was dried and triturated. The preparation was mixed with sucrose, treated with 75% alcohol, granulated, dried at 80°C, and made into granules^[16]. 1 mL herb liquor containing 1 g crude drug was ensured, and then the preparation was stored at 4°C.

Fluoxetine hydrochloride capsules (C₁₇H₁₈F₃NO·HCl) were produced by Apotex Inc., Canada, repacked by Liaoyuan Yadong Pharmaceutical Factory, specification: 20 mg/granule; permission number of import drugs H20040354.

Methods

Preparation of depression model rats

Depression model rats were established by a chronic stress method^[17-18]. Each rat was isolated in an individual cage, and underwent various stressors over 21 days, including swimming in cold water (4°C, 5 minutes), water deprivation (24 hours), a high temperature environment (45°C, 5 minutes), fasting diet (24 hours), tail-clamping (1 minute), weaving (once a second, 5 minutes), electric shock on a footplate (5 mV, one stimulus was done every 30 seconds, each for 10 seconds, totally 15 times), and daytime or nighttime inversion. Over these 21 days, one stressor was pseudorandomly chosen and given each day. Each kind of stressor was given 2–3 times. The same stressor was not given 2 days in a row. Thus, the rats could not predict which stressor they would receive. In the normal group, six rats were housed in each cage and allowed free access to food and water, but they did not receive any stressors.

Intragastric administration of *Kaiyu* Granule

The rats in the high-, moderate-, and low-dose *Kaiyu* Granule groups were intragastrically administered 12, 8, or 4 g crude drugs/kg *Kaiyu* Granule during chronic stress, separately at 50, 20, and 5 times the clinical dose^[1, 19]. The rats in the fluoxetine group were given 2 mg/kg fluoxetine hydrochloride capsules, which is seven times the clinical dose (0.333 mg/kg). The outer coating of the capsule was removed, and the drugs were dissolved in distilled water. The rats were intragastrically administered the drug once at 8 a.m. every day for 21

consecutive days^[20]. The rats in the normal and model groups were given 10 mL/g distilled water by intragastric administration at 8 a.m., once a day, for 21 consecutive days.

Behavior detection

Body weight: The body weights of the rats in each group were determined with an electronic balance before the experiment and after 21 days of stress.

Sucrose preference test: At 10:00 a.m., 1% sucrose water and plain water were separately laid around the sides of the cage in each group. The position of the water container was exchanged every 12 hours over 48 hours to acclimate the subjects to the container. After 24 hours of water deprivation and fasting, all rats were administered bottles of 1% sucrose water and plain water. The sucrose consumption percentage within 3 hours was calculated as: sucrose consumption percentage (%) = sucrose consumption/(sucrose + plain water consumption) × 100%.

Open field test: The open-field box was made of wood, with a length, width, and height of 80 cm × 80 cm × 40 cm, and contained 25 squares of equal area. The inner wall and undersurface were black. The test was conducted after model induction and after drug administration. The rats were placed in the center of an open-field box under quiet conditions at room temperature with soft light. The frequency of crossing the square was used to determine locomotor activity. Three or four claws entering the square was scored as 1. The frequency of rearing was determined by rearing activity. Removing two forelimbs from the ground (> 1 cm) once was scored 1. Each rat was measured once each session and the additional rat was not assessed until the box was cleared.

Preparation of specimens

After 21 days of daily stress, the rats were anesthetized with sodium pentobarbital 1 mL/200 g (Tianjin Pharmaceutical Group Xinzheng Co., Ltd., Xinzheng, Henan Province, China). By left ventricular intubation, the rats were fixed with saline and 4% paraformaldehyde (prepared with PBS). The brain was obtained by decapitation, postfixed in 4% paraformaldehyde for further use^[21], and then serially sliced into 6–8 μm-thick coronal sections with a cryostat. The brain sections containing the hippocampus^[22] were placed in 0.1 mol/L PBS^[23-24].

Immunocytochemical staining of GIRK1 expression in rat hippocampus

The sections were dewaxed, treated with 3% H₂O₂ at

room temperature for 10 minutes to deactivate endogenous enzymes, washed three times with distilled water, immersed in 0.01 mol/L citrate buffer (pH 6.0), and heated with a microwave oven. The power supply was cut off until boiling, with an interval of 5–10 minutes, repeated for 1–2 times. After cooling, the sections were washed twice with PBS (pH 7.2–7.6) and blocked with fetal bovine serum at room temperature for 20 minutes. Any unnecessary liquid was discarded. Without washing, the sections were incubated in mouse anti-rat GIRK1 monoclonal antibody (1:100; Shanghai Hengfei Biological Technology Co., Ltd., Shanghai, China) at 7°C for 1 hour, washed with PBS (2 minutes × 3), incubated with biotinylated goat anti-mouse IgG (1:50; Beijing Hongyuechuangxin Technology Co., Ltd., Beijing, China) at 37°C for 20 minutes, washed with PBS (2 minutes × 3). Subsequently, the sections were incubated in streptavidin-peroxidase complex at 37°C for 20 minutes, washed with PBS (5 minutes × 4), visualized with 3,3'-diaminobenzidine, lightly counterstained with hematoxylin, dehydrated, permeabilized, and mounted^[25]. Images of the sections were analyzed using a light microscope (Olympus, Japan) and high-definition color pathological image analysis system (Huida Instruments Co., Ltd., Hubei Province, China). Absorbance values were measured after the gray scale was regulated. Three visual fields of each section was selected, and the average value was calculated^[26-27].

In situ hybridization of GIRK1 mRNA expression in rat hippocampus

Each rat hippocampus was dewaxed. The sections were immersed in 0.1 mol/L PBS at room temperature (5 minutes × 3), washed with 0.1 mol/L glycine and 0.1 mol/L PBS for 5 minutes, at room temperature, followed by a wash with 0.4% Triton X-100-PBS for 10 minutes at room temperature to induce protein denaturation and to increase penetration of the probe. The sections were washed with 0.1 mol/L PBS (5 minutes × 3) at room temperature, digested with 1 μg/mL proteinase K 37°C for 30 minutes. Detected mRNA was exposed. The reaction was terminated by 4% paraformaldehyde for 5 minutes at room temperature and washed in 0.1 mol/L PBS (5 minutes × 3). Excess fixative solution was removed. The specimens were treated with 0.25% acetic anhydride (prepared by 0.1 mol/L triethanolamine) for 10 minutes at room temperature, prehybridized in prehybridization solution (5 × standard saline citrate, 50% formamide) at 37°C for 2 hours, and hybridized in hybridization solution at 42°C for 12–18 hours (the probe concentration was 250 ng/mL). Subsequently, the sections were washed with 4 × with standard saline citrate at

room temperature (10 minutes × 3), 2 × with standard saline citrate at room temperature (10 minutes × 3), 2 × with standard saline citrate + RNaseA (10 µg/mL) at 37°C for 30 minutes, 0.1 × with standard saline citrate at room temperature (10 minutes × 3), and washed with TSM1 at room temperature for 10 minutes. The sections were incubated with TSM2 containing anti-DIG antibody (1:1 000–3 000) at room temperature for 3 hours, washed with TSM1 at room temperature for 10 minutes, washed with TSM3 at room temperature for 5 minutes, and then visualized in TSM3 containing nitro blue tetrazolium and 5-bromo-4-chloro-3-indolyl phosphate for 3–6 hours in the dark. The reactions were terminated by adding TE buffer. The sections were placed on chrome-alum gelatin-coated slides at 37°C overnight, dehydrated, permeabilized, and mounted with neutral gum. All hybridization procedures were conducted after RNA enzyme was deactivated in accordance with a digoxin-labeled oligonucleotide probe *in situ* hybridization kit^[28-29] (Boster, Wuhan, Hubei Province, China). The average gray value was calculated using a light microscope (Olympus) and high-definition color pathological image analysis system^[30]. Three visual fields of each section was selected, and the average value was calculated^[22].

Statistical analysis

The data are expressed as mean ± SD, and analyzed using SPSS 13.0 software (SPSS, Chicago, IL, USA). Intergroup differences were compared with one-way analysis of variance. Paired comparisons were performed using two-sample *t*-tests. A value of *P* < 0.05 was considered statistically significant.

Research background: GIRK has been shown to directly couple to many inhibitory transmitter receptors, and it is a direct effector between the heart and many neurotransmitters in the brain.

Research frontiers: The mechanisms of many traditional Chinese drug compound preparations are unclear. This study investigated the effects of GIRK1 mRNA expression in the hippocampus of rats undergoing chronic stress, and discovered the partial mechanisms of *Kaiyu* Granule in treatment of depression.

Clinical significance: Results confirmed that *Kaiyu* Granule could improve depression symptom by affecting the expression of GIRK1. *Kaiyu* Granule is an effective drug for depression.

Academic terminology: Inwardly rectifying K⁺ channels are a specific subset of potassium selective ion channels and allow K⁺ to move more easily into rather than out of the cell.

Peer review: This study established depression model rats, used fluoxetine as a positive control, and found that *Kaiyu*

Granule obviously increased the expression of GIRK1 in the hippocampal CA3 and CA1 regions, and confirmed the effects of *Kaiyu* Granule against depression.
