

Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.

Session Title: The Crystal Ball: Clinical Characteristics, Bio-markers and Imaging to Predict Outcomes in COVID-19  
Abstract Category: 61. Spotlight on Special Topics: Coronavirus Disease (COVID-19)  
Presentation Number: 1120-11

Authors: *Osama Dasa, Chen Bai, Mamoun Mardini, Thomas A. Pearson, University of Florida, Gainesville, FL, USA*

**Background:** African Americans (AA) disproportionately suffered from higher incidence and worse outcomes of COVID-19 compared to White Americans (WA). We hypothesize that AA have excess cardiovascular comorbidities compared to WA, accounting for disparities in COVID-19 severity and death.

**Methods:** We examined 63,545 lab-confirmed COVID-19 cases from the One Florida Research Consortium’s sample of healthcare recipients through April, 2021. We assessed the prevalence of preexisting comorbidities and COVID-19 outcomes using EHR data. We used XGBoost machine learning algorithm based on the gradient boosting framework to predict COVID-19 outcomes. We evaluated the relationship across features and outcomes using SHAP values. Outcomes compared rates of ICU admission or all-cause death at index admission.

**Results:** Compared to WA, AA patients were more likely to be younger, female, and uninsured. AA patients had the highest comorbidity burden (mainly cardiovascular), as well as higher ICU admission, and death rates. The strongest outcome predictors were age, race, gender, poverty, and cardiometabolic diseases. AA race was the strongest predictor of adverse outcomes compared to other races (Figure 1).

**Conclusion:** Even after including a multitude of risk factors, a residual excess risk of adverse outcomes persists in AAs and requires further investigation. Such data are essential to identify high-risk subgroups benefitting from enhanced preventive and early therapeutic interventions.
