Purpose: The purpose of this study was to evaluate the efficacy of 360-degree suture trabeculotomy (360S-LOT) ab interno for treating open-angle glaucoma (OAG). Risk factors of surgical failure were examined.

Patients and methods: 360S-LOT ab interno alone was performed for patients with uncontrolled OAG, and combined 360S-LOT ab interno/phacoemulsification was performed for patients with controlled OAG with a visually significant cataract between March 2014 and September 2015 at a single center. The patients were prospectively followed for 2 years. The main outcome measures included 2-year intraocular pressure (IOP), number of anti-glaucoma medications used, postoperative complications, and predictive factors of surgical failure. Kaplan–Meier analysis was performed, with surgical success (with or without medication use) defined as postoperative IOP ≤ 15 mmHg and IOP reduction $\geq 20\%$ (criterion A) or IOP ≤ 12 mmHg and IOP reduction $\geq 30\%$ (criterion B). Predictive factors were evaluated using Cox proportional hazard ratios.

Results: A total of 64 eyes of 64 patients were included, and 50 (78%) eyes of 64 eyes underwent a phacoemulsification combination procedure. Surgery significantly reduced IOP from 18.4 ± 2.9 mmHg before surgery to 13.4 ± 3.0 mmHg after surgery ($P < 0.001$). Patients used an average of 1.8 ± 1.5 medications before surgery and 1.3 ± 1.5 medications after surgery ($P = 0.101$). No serious postoperative complications were observed. The probability of surgical success was 49.2% and 16.0% using criteria A and B, respectively. No risk factors of surgical failure were identified.

Conclusion: The 360S-LOT ab interno procedure is a favorable option for treating eyes with mild or moderate OAG.

Keywords: 360-degree suture trabeculotomy ab interno, open-angle glaucoma, minimally invasive glaucoma surgery, phacoemulsification

Introduction

Trabeculotomy lowers intraocular pressure (IOP) by reducing aqueous outflow resistance via ~ 120 -degree incision that is made in the trabecular meshwork and Schlemm's canal inner layer (without bleb formation).^{1–3} Unfortunately, trabeculotomy alone does not generally allow IOP to be maintained at < 15 mmHg after surgery, although IOP is further reduced when trabeculotomy is combined with cataract surgery.^{4–6}

A modified 360-degree suture trabeculotomy (360S-LOT)⁷ involves making an incision along the entire circumference of the trabecular meshwork and Schlemm's canal inner layer using 5-0 nylon suture. This procedure has a possibility to lower IOP significantly more than standard trabeculotomy.^{7,8} Since the resistance of the Schlemm's canal inner layer disappears upon circumferential incision, the postoperative IOP should theoretically be close to the episcleral venous pressure, which was reported to

be ~ 12 mmHg in both primary open-angle glaucoma (POAG) and normal tension glaucoma (NTG).⁹

We previously developed the 360S-LOT ab interno procedure that can preserve the conjunctiva and sclera, from a modified 360S-LOT ab externo technique, and analyzed short-term surgical safety and efficacy.¹⁰ Although the 360S-LOT ab interno procedure was found to be both safe and effective, mid-term outcomes and risk factors of surgical failure have not yet been examined. The current study prospectively examines the 2-year efficacy of the 360S-LOT ab interno procedure and investigates the factors that may contribute to surgical failure in patients with open-angle glaucoma (OAG).

Patients and methods

This prospective, nonrandomized, open-label, single-center, clinical trial was conducted at the Sato Eye and Internal Medicine Clinic (Arao City, Japan). All patients were enrolled between March 2014 and September 2015. The study protocol was reviewed and approved by the institutional review board and the ethics committee of Sato Eye and Internal Medicine Clinic. All study conduct adhered to the tenets of the Declaration of Helsinki, and written informed consent was obtained from all patients before any study examinations or procedures were performed.

Study patients

Patients were considered for enrollment in the 360S-LOT ab interno alone procedure if they had uncontrolled OAG with maximally tolerated anti-glaucoma medications. Furthermore, patients were considered for enrollment in the combined 360S-LOT ab interno/phacoemulsification with intraocular lens implant (PEA + IOL) procedure if they wished to undergo the combined procedure for a visually significant cataract that coexisted with controlled or uncontrolled glaucoma. This included patients with POAG, NTG, and exfoliation glaucoma (XFG). A cataract was considered to be visually significant if the patient complained of glare or halos and best-corrected visual acuity (BCVA) was 20/20 or worse. A POAG diagnosis was given if IOP was >21 mmHg, the angle was open (Shaffer grade 3 or 4), optic neuropathy was present, and typical matching disk and field changes had occurred. An NTG diagnosis was given using the same criteria, but IOP was ≤ 21 mmHg. An XFG diagnosis was given if exfoliation material had adhered to the lens surface or the iris–pupil margin, the angle was wide open in the presence of dense pigmentation, Sampaolesi's line was present, and optic neuropathy with matching visual field loss had

occurred. Patients were excluded from this study if they exhibited types of glaucoma other than POAG, NTG, or XFG or if they had a previous history of ocular trauma or glaucoma surgery. Patients were also excluded if they demonstrated the presence of other preexisting ocular diseases, a corneal abnormality that precluded reliable applanation tonometry, or the presence of a single functional eye.

360S-LOT ab interno procedure

All procedures were performed by a single surgeon (T.S.). Only one eye of each patient was included in this study. In some cases, patients did require bilateral surgery, but only the first eye operated on was included in analyses. The 360S-LOT ab interno procedure has been previously described in full.¹⁰ Briefly, a 1.7-mm temporal cornea incision was created and Schlemm's canal was incised at 15° on the nasal side using the Trabectome (NeoMedix Inc., Tustin, CA, USA). The rounded tip of a 5-0 nylon suture was then inserted into Schlemm's canal using 23-gage disposable forceps (Grieshaber Revolution[®] DSP[®]; Alcon Laboratories, Inc., Fort Worth, TX, USA). After passing the suture tip around the circumference of Schlemm's canal, the suture was pulled out through the same opening. The same forceps were then used to make a 360-degree incision in Schlemm's canal. The scleral wound integrity was assessed by closely monitoring for leakage. If necessary, standard phacoemulsification with PEA + IOL was performed following the 360S-LOT ab interno procedure through the same or a newly created upper corneal incision. Ocular integrity was again assessed via wound leakage examination.

Study examinations

All potential patients were screened for study eligibility using slit-lamp biomicroscopy, indirect ophthalmoscopy, manifest refraction, IOP measurement, corneal endothelial cell density (cells/mm²), and BCVA assessment (conventional Landolt ring chart). IOP was measured using a Goldmann tonometer. Baseline IOP was determined by the mean of the three most recent measurements, acquired on separate days within 1 month of surgery. Corneal endothelial cell density was examined using a noncontact specular microscope (SP-3000P; Topcon, Tokyo, Japan). Manifest refraction was measured using an auto ref-keratometer (ARK-530A; Nidek, Tokyo, Japan); all decimal visual acuity values were converted to the logarithm of the minimum angle of resolution (logMAR) for analyses.

All patients were examined on postoperative days 1, 2, and 3. Thereafter, patients were examined every 1–2 weeks until Month 1, monthly until Month 6, and every 2–3 months

until Month 24. The IOP was measured at every study visit. Patients were administered anti-glaucoma medications following surgery if IOP was higher than the desired range (<15 mmHg), as in the previous report.¹⁰

Outcome measures

Outcome measures were IOP at each study visit, the number of glaucoma medications used, cumulative surgical success rates (Kaplan–Meier life-table analysis), complication rates, and risk factors of surgical failure (multivariate analysis via Cox proportional hazard ratio [HR] model). Surgical success (with or without medication use) was defined as an IOP between 6 and 15 mmHg with a postoperative IOP reduction of at least 20% (criterion A) or an IOP between 6 and 12 mmHg with a postoperative IOP reduction of at least 30% (criterion B). A surgical failure was defined as not meeting success criteria at two consecutive follow-up visits at least 1 month after surgery or the need for additional glaucoma surgery. The IOP levels later than 1 month were used as determinants of surgical success so that short-term IOP fluctuations would not influence long-term surgical success rates. Risk factors of surgical failure were identified using the Cox proportional HR model with multivariate analysis. The variables for multivariate analysis were selected from variables with a *P*-value of <0.3, as determined by univariate analysis. Variables tested included age, sex, preoperative IOP, number of anti-glaucoma medications, glaucoma type, lens status, past intraocular surgeries, selective laser trabeculoplasty, and the phacoemulsification combination procedure.

Procedure safety

Safety measures included intra- and postoperative complication rates and BCVA 2 years after surgery. Examined postoperative complications included hyphema, shallow chamber, wound leaks, IOP spikes (IOP \geq 30 mmHg within 1 month of 360S-LOT ab interno), hypotony (IOP \leq 5 mmHg), infection, decreased corneal endothelial cell density, and vision loss.

Statistical analyses

The JMP statistical package (version 13; SAS Institute Inc., Cary, NC, USA) was used to perform all data analyses. Continuous data were expressed as mean \pm SD and were examined using paired *t*-tests and Wilcoxon signed-rank tests as appropriate. Categorical data were expressed as n (%) and were examined using Fisher's exact test. The Kaplan–Meier survival curve analysis was used to evaluate the cumulative

probability of success, and a log-rank test was used for comparison of the 360S-LOT ab interno procedure and the combined 360S-LOT ab interno/phacoemulsification procedure. Statistical significance was defined as *P* < 0.05.

Results

Baseline patient characteristics

The 360S-LOT ab interno procedure was performed on 83 eyes between March 2014 and September 2015. In all, 19 patients were excluded because they did not have OAG (9 eyes) or had already had the fellow eye included in this study (10 eyes). In the overall study, 14 of 64 (22%) eyes were lost to follow-up by 2 years; 50 eyes of 50 patients (20 males, 73.5 \pm 9.2 years old) reached the 2-year point. Preoperative ocular characteristics and treatment information of patients are summarized in Table 1. The 360S-LOT ab interno procedure was performed alone in 19 (29.7%) eyes and in combination with phacoemulsification in 45 (70.3%) eyes.

Outcomes

In 50 eyes of 50 patients that underwent follow-up for 2 years, surgery significantly reduced IOP from 18.4 \pm 2.9 mmHg to 13.4 \pm 3.5 mmHg after 1 year (27.2% reduction) and to 13.4 \pm 3.0 mmHg after 2 years (27.2% reduction, both *P* < 0.001; Table 2 and Figure 1). In eyes that underwent the 360S-LOT ab interno alone procedure, IOP was significantly reduced from 19.1 \pm 2.2 mmHg before surgery to 14.9 \pm 3.0 mmHg 1 year after surgery (22.0% reduction) and 14.6 \pm 2.9 mmHg 2 years after surgery (23.6% reduction, both *P* < 0.001). In eyes that underwent a combined 360S-LOT ab interno/phacoemulsification procedure, IOP was significantly reduced from 18.1 \pm 3.2 mmHg before surgery to 12.7 \pm 3.6 mmHg 1 year after surgery (29.3% reduction) and 12.7 \pm 2.9 mmHg 2 years after surgery (28.5% reduction, both *P* < 0.001).

The number of anti-glaucoma medications used was 1.8 \pm 1.5 before surgery and 0.9 \pm 1.2 (*P* < 0.001) and 1.3 \pm 1.5 (*P* = 0.101) 1 and 2 years after surgery, respectively. In eyes that underwent the 360S-LOT ab interno procedure alone, the number of anti-glaucoma medications used was also significantly reduced from 3.3 \pm 0.8 before surgery to 1.7 \pm 1.3 (*P* < 0.001) and 2.2 \pm 1.4 (*P* = 0.001) 1 and 2 years after surgery, respectively. In eyes that underwent a combined 360S-LOT ab interno/phacoemulsification procedure, the number of anti-glaucoma medications was significantly reduced from 1.0 \pm 1.2 before surgery to 0.4 \pm 0.9 1 year after surgery (*P* = 0.021). However, the number of anti-glaucoma medications used 2 years after surgery was

0.8 ± 1.3, which was not significantly different from that before surgery ($P = 0.420$).

The surgical success rate, based on an IOP of <15 mmHg, which was set as the postoperative target with or without medication use, was 64.2%. Figure 2 shows surgical success,

using the Kaplan–Meier survival analysis, for both criteria A and B. Two years after 360S-LOT ab interno, the surgical success rate was 49.2% for criterion A and 16.0% for criterion B. Although the success rate of the combined 360S-LOT ab interno/phacoemulsification procedure was significantly

higher than that of the 360S-LOT ab interno alone procedure in criterion A ($P = 0.043$), there was no significant difference between both groups in criterion B ($P = 0.070$).

Univariate analysis (Table 3) indicated that for condition A, ≥ 2 anti-glaucoma medications and 360S-LOT ab interno alone were significant risk factors of surgical failure ($P = 0.027$ and $P = 0.043$, respectively). Variables with P -values of < 0.3 were age, female sex, and past history ($P = 0.087$, $P = 0.110$, and $P = 0.053$, respectively). Although univariate analysis showed that no variable was a significant risk factor of surgical failure for criterion B, variables with P -values of < 0.3 were age, ≥ 2 anti-glaucoma

medications, past history, and 360S-LOT ab interno alone ($P = 0.232$, $P = 0.165$, $P = 0.247$, and $P = 0.070$, respectively). Multivariate analysis (Cox proportional HR model) did not reveal any factors that were predictive of surgical success or failure (Tables 4 and 5).

Safety

No patient experienced any severe complications during surgery or the 2-year follow-up period. Additionally, no significant safety differences were observed between eyes that underwent 360S-LOT ab interno alone and those that underwent a combined 360S-LOT ab interno/phacoemulsification procedure (Table 6). It should be noted that 25 (50.0%) eyes had a hyphema 1 day after surgery. The hyphema spontaneously resolved by 1 month in all but two eyes, which required anterior chamber washing at 1 week because the hyphema was massive and was causing IOP spikes. In addition to these two eyes, 12 other eyes also experienced IOP spikes (14 eyes in total [28%]) within the first month after surgery. In these 12 eyes, a temporary systemic carbonic anhydrase inhibitor was used to lower IOP, which returned to within the normal range within 1 week.

The endothelial cell density was $2,460.1 \pm 361.0$ cells/mm² after 2 years of surgery, a $4.9\% \pm 7.6\%$ reduction from that before surgery. One (2%) eye required a trabeculectomy because of uncontrolled IOP 22 months after surgery. In the group that underwent combined 360S-LOT ab interno/phacoemulsification procedure, logMAR BCVA significantly improved from 0.34 ± 0.36 (Snellen equivalent: 20/44) before surgery to 0.14 ± 0.26 (Snellen equivalent: 20/28) 2 years after surgery ($P = 0.001$). Eyes that underwent 360S-LOT ab

Figure 2 Kaplan–Meier survival curves for surgical success using (A) criterion A (IOP between 6 and 15 mmHg and IOP reduction $\geq 20\%$) and (B) criterion B (IOP between 6 and 12 mmHg and IOP reduction $\geq 30\%$).

Notes: Criteria were applied independent of anti-glaucoma medication use. Two-years after surgery, the success rates using criteria A and B were 49.2% and 16.0%, respectively. Lines representing all patients (—) and 360S-LOT ab interno with (....) and without (----) PEA + IOL are shown for reference.

interno alone did not have a significant change in BCVA 2 years following surgery (preoperative: 0.06 ± 0.17 [Snellen equivalent: 20/23], postoperative: 0.11 ± 0.15 [Snellen equivalent: 20/26]; $P = 0.073$).

Discussion

This prospective study evaluated the 2-year efficacy of the 360S-LOT ab interno procedure performed to treat OAG. Risk factors of surgical failure were also examined. The 360S-LOT ab interno procedure significantly reduced IOP at both the 1- and 2-year time points compared to the baseline values. No prognostic factors for 360S-LOT ab interno failure were identified by the Cox proportional HR model analysis.

Prior studies have examined the efficacy of a modified 360S-LOT ab externo procedure. One year following surgery, IOP was 10.9 mmHg in eyes with XFG¹¹ and

14.5 mmHg in eyes with OAG.¹² Two years following surgery, IOP was ~13 mmHg in eyes with OAG.¹³ Additionally, Grover et al¹⁴ found that gonioscopy-assisted transluminal trabeculotomy, which includes creating a 360-degree trabeculotomy with a thermally blunted suture or microcatheter, reduced IOP to 12.4–16.2 mmHg 1 year after surgery and ~16 mmHg 2 years after surgery.¹⁵ This was even true in patients who had undergone prior incisional glaucoma surgery. Our results with the 360S-LOT ab interno procedure were slightly superior to those of the previous study by Grover et al, where an IOP of 13.4 mmHg was observed at 2 years after surgery. We suspect that, in the present study, the preoperative IOP was lower and the patients had no previous glaucoma surgery, in contrast with the prior study.

However, the postoperative IOP in the present study was 13.4 mmHg at 2 years after surgery, higher than the episcleral venous pressure, despite nearly elimination of the resistance of the inner layer of the circumferential Schlemm's canal. Episcleral venous pressures in POAG and NTG patients have been reported as 12.1 ± 0.5 mmHg and 11.6 ± 0.4 mmHg, respectively, both of which are significantly higher than the episcleral venous pressure of normal eyes (9.5 ± 0.2 mmHg).⁹ Thus, we suspect that resistance may be increased by inflammation or coagula occurring in the early postoperative period or by trabecular meshwork and Schlemm's canal inner layer incision closure during the wound healing process.¹⁶

Nearly half (45.8%) of patients in the current study had a postoperative IOP of ≤ 15 mmHg and a postoperative IOP reduction of at least 20% 2 years after surgery. Therefore, the 360S-LOT ab interno procedure may be a useful option for treating mild- to moderate-stage OAG. However, because only 16.0% of patients had an IOP of ≤ 12 mmHg with a postoperative IOP reduction of $\geq 30\%$, this procedure is likely not useful for treating late-stage glaucoma. Our mid-term success rates with the ab interno procedure were likely similar or better than those previously reported for standard trabeculotomy (ab externo). Success rates of the ab externo procedure, which involves incising the trabecular meshwork and Schlemm's canal inner layer at 120° , decreased over the 5 years following surgery.¹⁶ This efficacy decrease over time was likely caused by trabecular meshwork and Schlemm's canal inner layer incision closure that occurred during the wound healing process. It is possible that the wider trabecular meshwork and Schlemm's canal inner layer opening that is made with the

Table 6 Intraoperative and postoperative complications following 360S-LOT ab interno

	All patients	360S-LOT ab interno alone	360S-LOT ab interno + PEA + IOL	P-value
n, patients/eyes	50/50	17/17	33/33	NA
Intraoperative blood reflux, n (%)	50 (100)	17 (100)	33 (100)	1.000
HypHEMA, n (%)				0.072
Day 1	25 (50)	12 (71)	13 (39)	
Week 1	12 (24)	7 (41)	5 (15)	
Week 2	4 (8)	2 (12)	2 (6)	
Shallow chamber	0 (0)	0 (0)	0 (0)	
Wound leaks	0 (0)	0 (0)	0 (0)	1.000
IOP spike (>30 mmHg), n (%)	14 (28)	4 (24)	10 (36)	0.755
Hypotony (IOP <5 mmHg)	0 (0)	0 (0)	0 (0)	1.000
Infection	0 (0)	0 (0)	0 (0)	1.000
Corneal endothelial cell density reduction	$4.9\% \pm 7.6\%$	$5.2\% \pm 5.0\%$	$4.8\% \pm 8.6\%$	0.859
Anterior chamber washing out, n (%)	2 (4)	1 (6)	1 (3)	1.000
Subsequent glaucoma surgery, n (%)	1 (2)	1 (6)	0 (0)	0.340

Note: Corneal endothelial cell density reduction is expressed as mean \pm SD.

Abbreviations: 360S-LOT, 360-degree suture trabeculotomy; PEA + IOL, phacoemulsification with intraocular lens implant; NA, not applicable; IOP, intraocular pressure.

360-degree incision has a lower closure rate than the opening made with the 120-degree incision. On the other hand, Manabe et al¹² reported that the 150-degree or more extent of the incision in the Schlemm's canal during S-LOT ab externo did not affect the reduction in IOP at 1 year postoperatively. We are currently prospectively investigating the relationship between Schlemm's canal incision width and the postoperative IOP reduction, because there is a possibility that 360-degree incision in the Schlemm's canal is too invasive.

Although no prognostic factors for 360S-LOT ab interno failure were identified by the Cox proportional HR model, univariate analysis by the Kaplan–Meier survival analysis method revealed that ≥ 2 anti-glaucoma medications and 360S-LOT ab interno alone were both significant risk factors of surgical failure. Additionally, the IOP was significantly lower in the 360S-LOT ab interno with phacoemulsification group than in the 360S-LOT ab interno group throughout the follow-up period, 1 month after surgery, and the success rate of the combined 360S-LOT ab interno/phacoemulsification procedure was significantly higher than that of the 360S-LOT ab interno alone procedure in criterion A. Although the phacoemulsification procedure alone reduces IOP in glaucomatous eyes,^{17,18} an earlier report discussed the difficulties of separating the effects of phacoemulsification and glaucoma surgeries because the two procedures have different goals.¹⁹ Many patients who require 360S-LOT ab interno alone have uncontrolled IOP even though they are using anti-glaucoma medications. In these patients, the surgical goal is to lower IOP. However, patients who undergo 360S-LOT ab interno in combination with phacoemulsification procedure generally have a visually significant cataract but controlled IOP. These patients have a surgical goal of increasing vision (from cataract removal) and reducing the number of anti-glaucoma medications.

No serious complications (eg, shallow anterior chamber, choroidal detachment, infection, or wound leakage) occurred in any of our patients. The most frequent postoperative complications observed were hyphema and IOP spikes, but the incidences of hyphema and IOP spikes were not particularly high, and in most eyes, these complications were easily controlled. Therefore, the 360S-LOT ab interno is likely a safe procedure, but careful follow-up is needed within the first postoperative month.

The current study has several limitations. First, our sample size was small. Second, this study was not controlled. Third, the mean preoperative IOP was < 21 mmHg, which is not excessively high. The Tajimi Study in Japan reported a POAG prevalence of 3.6% in patients with an IOP of ≤ 21 mmHg, which was significantly higher than the POAG prevalence of 0.3% in patients with an IOP

of > 21 mmHg.²⁰ Accordingly, there are many cases in which treatments are performed in patients with OAG but not a high IOP in Japan, similar to that found in this study. Because of these limitations, additional research is needed on a larger group of patients to better understand long-term efficacy of the 360S-LOT ab interno procedure.

Conclusion

The current study demonstrates that the 360S-LOT ab interno procedure is likely a safe and effective treatment for OAG over the midterm (at least 2 years). Thus, this procedure should be considered for surgically managing mild to moderate OAG. It should be noted that further studies are needed to validate our findings.
