ABSTRACT Listeria monocytogenes is an important foodborne pathogen that causes listeriosis. Here, we report the draft genome sequences of seven *L. monocytogenes* strains isolated from food, environmental, and clinical sources. Sequence differences at the genome level may help in understanding why these strains displayed different virulence and stress response characteristics.

Listeria monocytogenes is a Gram-positive bacterial pathogen that is present ubiquitously in the environment. *L. monocytogenes* is often associated with foods such as ready-to-eat meats, raw produce, and dairy products (1). It is a foodborne pathogen that can cause listeriosis with a high mortality rate. *L. monocytogenes* is very difficult to control in the food industry since it can survive under very harsh conditions, such as high salt, low pH, and low temperature (2, 3). Strains of *L. monocytogenes* isolated from food, environmental, and clinical sources have displayed different serotypes, stress responses, and virulence potentials. In the current study, isolates from food were serotypes 1/2a, 1/2b, or 1/2c, whereas the clinical isolate was serotype 4b (Table 1), similar to many other reported clinical isolates (4).

Here, we report the draft genome sequences of seven *L. monocytogenes* strains isolated from food, environmental, and clinical samples (Table 1) which belong to different serotypes and have shown different stress response and virulence profiles. For example, both strains LMB33029 and LMB33868 displayed sensitivity to salt (10% NaCl) treatment, whereas strain LMB33029 was more sensitive to nisin (125 μ g/ml) treatment than is strain LMB33868. LMB33761, LMB57147, and LMB33724 displayed weak ability to form biofilms as shown by biofilm assays (5). However, as determined by a plaque assay, strains LMB33724 (6). LMB33922 and LMB33123 had a strong biofilm-forming ability and a virulence potential similar to that of LMB33724 but less than that of LMB33761 and LMB57147 (our unpublished data).

For whole-genome sequencing, genomic DNA was extracted using the DNeasy blood and tissue kit (Qiagen, Valencia, CA) from 1 ml of overnight culture grown in tryptic soy broth (TSB), and the concentrations of genomic DNA were measured using a Qubit 3.0 fluorometer (Life Technologies, Carlsbad, CA). Library preparation was carried out using the Nextera DNA Flex library prep kit (Illumina, San Diego, CA) according to the manufacturer's instructions. Libraries generated with 600-bp frag-

ments were quantified by a Qubit 3.0 fluorometer (Life Technologies), and the denatured pooled libraries were loaded onto a flow cell for cluster generation. Sequencing was performed using the Illumina MiniSeq platform with a 2 \times 150-bp paired-end read protocol with more than 151 \times coverage. The quality of the sequences was assessed by FastQC and assembled using the SPAdes genome assembler (version 3.9.0) (7), available on the BaseSpace cloud platform (BaseSpace software version 2.0.2018) from Illumina. Virulence factors, multilocus sequence types (MLST), rRNA, tRNA, genes, pseudogenes, and coding sequences (CDSs) were determined using the Illumina Bacterial Analysis Pipeline (version 1.0.4) and the NCBI Prokaryotic Genome Annotation Pipeline (PGAP) version 4.3 (8). A description of the characteristics of the seven *L. monocytogenes* strains is presented in Table 1. Whole-genome sequence information can be used to identify the sequence differences among these strains and assist in understanding why these strains have displayed different virulence potentials and stress responses.

Data availability. The draft genome sequences reported here have been deposited in DDBJ/ENA/GenBank under the accession and BioProject numbers listed in Table 1. The versions described in this paper are the first versions.
