Abstract

Objective To quantify the prevalence of adverse childhood experiences (ACEs) among a diverse urban cohort of pregnant women.

Study Design The ACE survey was self-administered to 600 women categorized evenly between the waiting room, private examination rooms, and CenteringPregnancy group spaces. The percentage of women willing to complete the survey per location was compared using chi-square tests, and the mean ACE score per arm was compared using Wilcoxon's rank-sum test.

Results Of the 660 women approached for participation, 5% declined; 67% reported ≥ 1 ACE exposure and 19% reported an ACE score of ≥ 4 . By domain, 59% experienced household dysfunction, 25% abuse, and 25% neglect. Women in the waiting room were more likely to decline participation ($p < 0.01$), and those participating in the postpartum inpatient arm had a significantly lower proportion affirming 8 of 10 ACE questions, were less likely to report ≥ 1 ACE, and had a lower mean ACE score when compared with the outpatient arm ($p < 0.01$).

Conclusion The prevalence of ACEs in this diverse pregnant cohort was high. The ideal locations to distribute the survey are the outpatient examination rooms.

In 1998, Felitti et al published the landmark Adverse Childhood Experiences (ACE) Study,¹ in which they reported a strong dose-dependent relationship between one's exposure to abuse and dysfunction in childhood, as measured by an ACE score, and risk factors for the leading causes of death in adults. This ACE score was calculated based on the number of "yes" responses on a 10-item survey regarding one's exposure to three domains of adverse experiences before the age of 18: abuse, neglect, and household dysfunction. Their original cohort of more than 8,000 participants, who were predominantly older, non-Hispanic White, and well-educated, remains the population from which the majority of subsequent ACE analyses have been

reported. This ACE work is critically important for those practicing in the clinical arena, particularly when considered in context to the widely held theory of multiple determinants of health outcomes. This theory suggests that only 10% of all health outcomes may be attributed to actual medical care; in contrast, 40 to 60% are attributed to social and behavioral factors.²

Given the known association between maternal stress and markers of poor social support with adverse pregnancy outcomes,^{3–5} the relationship between formal ACE scores and adverse pregnancy outcomes is of key public health interest. Secondary analyses from the original cohort report a dose-dependent relationship between ACE scores and rates

of adolescent pregnancy,^{6,7} unintended pregnancy,⁸ and fetal death.^{6,7} However, these scores were obtained from a survey mailed to women who were largely remote from their reproductive years. Other investigators in the United States, Canada, and Switzerland have correlated ACE scores to alcohol use during pregnancy, smoking, and spontaneous preterm birth, but they administered the survey retrospectively after pregnancy.^{9–11} Very few investigators have administered the survey during pregnancy,^{12–14} and none have investigated the impact of the location where the survey was administered on a woman's willingness to complete it.

Therefore, the primary objective of our study was to quantify the prevalence of ACE exposures among a racially diverse, low-to-middle socioeconomic status pregnant urban cohort. Secondary objectives were to determine the setting in which women were more likely to complete the survey and whether the setting affected the mean reported ACE score. Furthermore, within the subset of postpartum patients, we sought to determine whether an absolute ACE score or a particular ACE domain was associated with preterm delivery.

Materials and Methods

Eligible patients were those 18 years or older receiving prenatal care from an ambulatory women's health clinic run at a tertiary academic medical center in the American South. This clinic serves a diverse population; of the 1,229 women who came for routine prenatal care over the 3-month study period, 44.9% were Caucasian, 28.6% were African-American, 22.5% were Hispanic, and 1% other. Additionally, 64% received care under Medicaid and 21% were uninsured. The inpatient arm of the study was performed on the postpartum units of the associated large tertiary care teaching hospital.

A convenience sample of 600 was chosen, representing more than 20% of the clinic's annual patient population, and divided by location where the survey was administered as follows: 300 inpatient and 300 outpatient, with the outpatient arm divided equally ($N = 100$) between administration in the clinic's waiting rooms, private examination rooms, and the CenteringPregnancy group spaces. In order to prevent duplicative sampling, Participants were not given a survey if they reported having already completed one previously.

For the inpatient arm, a research team member went to each postpartum room and asked the patient if she would be willing to fill out the anonymous 10-question survey on ACEs. Patients were offered a small edible incentive for participating. Completed surveys were then collected in a drop box with the survey questions and answers folded inward. A similar technique was used in the ambulatory setting.

The survey used for this study (► Fig. 1) was derived directly from the published ACE survey and was made available in both English and Spanish. Additional questions included patient's age and self-reported race. For postpartum patients, the survey also inquired about gestational age at the time of delivery and the newborn's birth weight (in ounces, which was converted to grams). Preterm delivery was defined as delivery less than 37 weeks' gestational age. No patient identifiers were used for any arm of the study.

Both participation rates and the number of complete versus incomplete forms were tracked and categorized by location completed. Consistent with other investigators, for any of the 10 ACE questions that were unanswered, a "no" response was assumed. We then calculated overall ACE scores, defined as the sum of "yes" answers (plausible range: 1–10), and ACE score within each of the three ACE domains (abuse, neglect, and household dysfunction). We compared the proportions of outpatient versus inpatient respondents affirming each ACE domain and ACE category using chi-square tests, and the mean ACE scores using Wilcoxon's rank-sum tests. For those women completing the form in the postpartum setting, we compared the proportions of preterm versus term births affirming each ACE category using chi-square tests (Fisher's exact tests for cell sizes < 5). We also compared mean ACE scores and the proportion of women affirming each ACE domain of preterm versus term births with the Wilcoxon's rank-sum test and chi-square test, respectively. Statistical analysis was performed with Stata version 13 (College Station, TX).

Results

A total of 660 patients were approached for participation in the study (► Fig. 2). Of the 660 women asked, 35 (5%) declined. Of those agreeing to complete the survey, 12 women were discharged from the hospital or left the waiting room before the survey could be collected and 12 were determined ineligible after survey completion because they reported being less than 18 years old. The final sample included 601 surveys. Of the final analysis group, 567 (94%) provided an answer to all 10 ACE questions.

The demographics of the participants were representative of the entire ambulatory clinic population (► Table 1). The age of participants ranged from 18 to 43 years, with a mean age of 25.7 years (standard deviation: 5.3 years). Race and age characteristics of the outpatient and inpatient groups did not differ.

Of the analytic sample, 201 (33%) reported no exposure to any ACEs, whereas 116 (19%) reported exposure to four or more ACEs. Overall, the most prevalent experience was parental separation or divorce, as reported by 305 women (50.7%). When viewed by domain of ACE score, 59.4% of the population had experienced household dysfunction, 25.5% experienced abuse, and 25.3% experienced neglect (► Table 2). Total ACE scores were comparable to the scores published by Felitti et al in the original ACE study.¹

The proportion of women agreeing to complete the survey differed by location. Of those women who were approached in the outpatient waiting room, 13.3% declined compared with less than 4% of women approached in the hospital (inpatient) postpartum or in either an outpatient examination room or CenteringPregnancy group ($p < 0.01$).

Additionally, the postpartum inpatient arm had a significantly lower proportion affirming 8 out of 10 of the questions ($p < 0.05$), a lower proportion of women reporting at least one ACE ($p < 0.001$) (► Table 3), and a lower mean ACE score ($p < 0.01$).

Adverse Childhood Experience (ACE) Questionnaire

Finding your ACE Score ra hbr 10 24 06

While you were growing up, during your first 18 years of life:

1. Did a parent or other adult in the household **often** ...
Swear at you, insult you, put you down, or humiliate you?
or
Act in a way that made you afraid that you might be physically hurt?
Yes No If yes enter 1 _____
2. Did a parent or other adult in the household **often** ...
Push, grab, slap, or throw something at you?
or
Ever hit you so hard that you had marks or were injured?
Yes No If yes enter 1 _____
3. Did an adult or person at least 5 years older than you **ever**...
Touch or fondle you or have you touch their body in a sexual way?
or
Try to or actually have oral, anal, or vaginal sex with you?
Yes No If yes enter 1 _____
4. Did you **often** feel that ...
No one in your family loved you or thought you were important or special?
or
Your family didn't look out for each other, feel close to each other, or support each other?
Yes No If yes enter 1 _____
5. Did you **often** feel that ...
You didn't have enough to eat, had to wear dirty clothes, and had no one to protect you?
or
Your parents were too drunk or high to take care of you or take you to the doctor if you needed it?
Yes No If yes enter 1 _____
6. Were your parents **ever** separated or divorced?
Yes No If yes enter 1 _____
7. Was your mother or stepmother:
Often pushed, grabbed, slapped, or had something thrown at her?
or
Sometimes or often kicked, bitten, hit with a fist, or hit with something hard?
or
Ever repeatedly hit over at least a few minutes or threatened with a gun or knife?
Yes No If yes enter 1 _____
8. Did you live with anyone who was a problem drinker or alcoholic or who used street drugs?
Yes No If yes enter 1 _____
9. Was a household member depressed or mentally ill or did a household member attempt suicide?
Yes No If yes enter 1 _____
10. Did a household member go to prison?
Yes No If yes enter 1 _____

Now add up your "Yes" answers: _____ This is your ACE Score

Fig. 1 Adverse childhood experience survey.

Of the 301 surveys completed postpartum, 277 (92%) reported the gestational age at which they delivered. Of those 277, the average gestational age was 38.7 weeks, with 22 (8%) delivered preterm. The prevalence of preterm deliveries captured by this study was lower than that reported for our institution, state, and nation at close to 12%. The preterm and term cohorts did not significantly differ in proportions affirming individual ACE categories or mean ACE scores.

Discussion

In this racially diverse population of pregnant women, the prevalence of ACEs was high, with 67% of the population exposed to at least one ACE. ACE scores of ≥ 4 , associated with the highest risk for adverse outcomes in many studies,^{1,11} were reported by nearly one in five women. By domain, 59% of women experienced household dysfunction, 25% had been

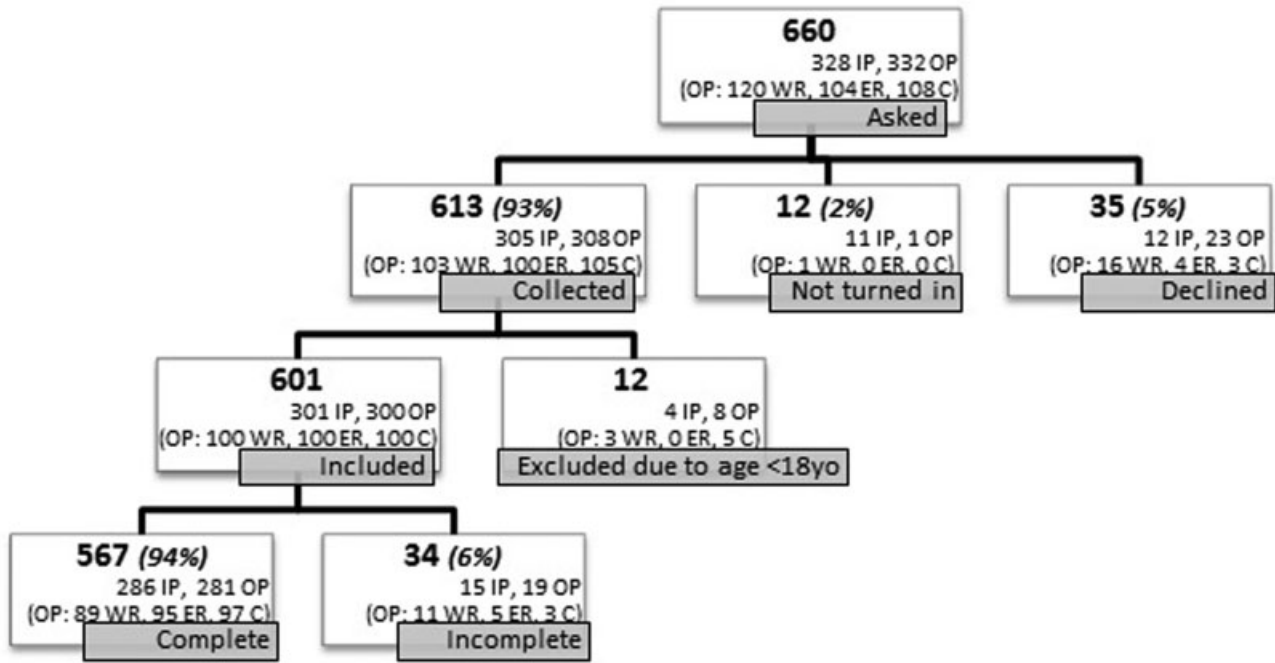

Fig. 2 Adverse childhood experience (ACE) study participation. C, centering; ER, examination room; IP, inpatient; OP, outpatient, WR; waiting room. A form was considered complete if all 10 ACE questions were answered, even if there was missing demographic information.

abused, and 25% had been neglected. This represents a significant emotional and physiological burden,⁸ and potentially a critical area for counseling and intervention in the prenatal setting.

Ours is the first study to report the location where women are most likely to complete a self-administered ACE survey in the puerperium, providing a helpful framework for future investigations. Women approached in the waiting room

setting were more likely to decline participation (13.3% compared with <4%), though overall acceptance of the survey was very high (95%). Those approached in the waiting room have less privacy than in other settings, potentially accounting for their higher refusal rates. For participants in the postpartum arm, the influence of stress and hormones during pregnancy versus after birth may have had an effect on how women responded, especially to questions on neglect

and emotional abuse. If the ACE survey is to be used as a screening tool, its use prenatally may be preferred. Due to comparable participation rates in the examination rooms and CenteringPregnancy group spaces, these are the ideal locations to distribute the survey.

Our work confirms and extends the relatively limited literature around ACE ascertainment during an ongoing pregnancy. Smith et al used trained interviewers to administer a modified version of the ACE survey to a large U.S. cohort at 28 weeks' gestation and reported a low refusal and incomplete survey rate (1.2%).¹⁴ However, their study population differed from ours in that their participants were predominantly white (76%) and married or living with a partner (90%). Drevin et al mailed the ACE survey to the homes of a Swedish cohort during the third trimester and reported a modest response rate ($N = 142$; 61%).¹³ Finally, Bublitz and Stroud reported a small population of patients ($N = 41$) who self-administered the survey around 20 weeks' gestation.¹⁵

We were unable to confirm the results of other studies, suggesting a significant association between higher ACE score and lower gestational age at birth.^{9,14} The preterm birth rate reported by our postpartum cohort was lower than

anticipated, which may have been due in part to an unintended selection bias created by collecting surveys only from participants who were in their postpartum rooms during normal neonatal intensive care unit visiting hours. Another source of bias may have been due to recall bias, as not all patients accurately report their gestational age at delivery. Furthermore, there were 24 (8%) of the 301 participating postpartum patients who did not record their gestational age at delivery, limiting the sample size further.

Overall, this study provides a strong foundation for future studies measuring the association between ACE scores and adverse pregnancy outcomes. We conclude that the ACE survey is readily completed by pregnant women in the ambulatory care setting, particularly in the rooms where they will receive their care, and that the prevalence of ACEs is high in a diverse urban cohort. Finally, we hypothesize that following additional research, this instrument may well provide a simple mechanism to identify women at the highest risk for adverse pregnancy outcomes.
