A novel green process for tannic acid hydrolysis using an internally sulfonated hollow polystyrene sphere as catalyst

Qionglin Luo,^{ab} Shunqin Zeng,^b You Shu,^{ab} Zaihui Fu,^a Hongran Zhao^c and Shengpei Su^{id}*^a

A polystyrene-hollow sphere catalyst was prepared by treating polystyrene-encapsulated calcium carbonate particles with concentrated hydrochloric acid. This catalyst was characterized using TGA, FT-IR, optical microscope, SEM-EDX and XPS. Evidences from SEM-EDX and XPS analyses indicated that the sulfonate groups were on the inner surface of the polystyrene hollow sphere. The polystyrene hollow spheres were used as catalyst in the hydrolysis of tannic acid. Reaction conditions including the reaction temperature and time, loading of catalyst, ratio of tannic acid to H₂O and number of recycles were optimized. A high yield of gallic acid was obtained as the reaction performed under the following conditions: a temperature of 80 °C, a molar ratio of tannic acid to H₂O of 1 : 3, and a catalyst loading of 7% w/w (based on the mass of tannic acid). This catalyst showed excellent catalytic performance, easy separation, high stability and good reusability. This work provides a new strategy for the controllable synthesis of polystyrene hollow structures with sulfonic groups on the inner surface and an excellent and prospective catalyst for the production of gallic acid through hydrolysis of tannic acid.

Introduction

Gallic acid is an important chemical that has various properties, such as anti-fungal, anti-viral, antioxidant, and anti-cancer activities (Fiuza *et al.*, 2004; Zaheer *et al.*, 2010).¹⁻³ It is widely used in organic synthesis, pharmaceuticals, food *etc.*⁴⁻⁶ Gallic acid is mainly produced by the hydrolysis of tannic acid, a specific form of tannin obtained from Chinese gall. There are a few typical catalysts used for hydrolysis of tannic acid including inorganic bases,⁷ inorganic acids,⁸ enzymes, and sulfonic ionic resins.⁹ In the cases using inorganic bases and acids as catalysts, a lot of wastewater is produced, which is difficult to be treated. In addition, corrosion of the equipment and tedious purification are also faced in typical production process. In the case using enzyme⁹⁻¹² as catalyst, shortages including high cost of tannase, deactivation of enzyme and non-recyclable, low efficiency limit the application of the enzymatic method for gallic acid production in industry. Strongly acidic ion exchange resins could be useful in the sulfonic catalyzed hydrolysis of tannic acid, but commercialized ionic exchange resins still

cannot improve the efficiency of tannic acid hydrolysis due to following reasons: the absence of specific affinity between the reactant molecules and the ion exchange resins; the lower diffusion and concentration of reactant inside the resin cavities because of the large size of tannic molecules and relative higher cross-link density of ionic resins. Thus, environmentally friendly catalysts with high efficiency are need for the industrial production of gallic acid from tannic acid. In fact, there are a number of previous studies where sulfonated solid acids were prepared and used in biomass-related reactions.¹³⁻¹⁶

In this paper, a polystyrene hollow sphere with sulfonic groups on the inner surface was prepared to improve the diffusion of reactants, and the structure of the polystyrene hollow sphere was characterized. In addition, its catalytic performance was tested for the hydrolysis of tannic acid.

Experimental section

Materials

Light calcium carbonate ($2\ \mu\text{m} < d < 5\ \mu\text{m}$) was purchased from Zhangjiajie Hengliang New Material Technology Co., Ltd. (Hunan Province, China). Analytical grade styrene and divinylbenzene were purchased from Shanghai Yongda Chemical Reagent Co., Ltd. (Shanghai, China). Analytical grade vinyl benzenesulfonic acid was purchased from Shanghai Aladdin Reagent Co., Ltd. (Shanghai, China). Benzoyl peroxide (BPO), methyl alcohol, phosphoric acid, AgNO₃, NaOH and NaCl were purchased from Tianjin Chemical Reagent Co., Ltd. (Tianjin,

China). Tannic acid (>95%) was purchased from Zhangjiajie JiuRui Biological Technology Co., Ltd. (Hunan Province, China). Distilled water was used throughout this experiment. All chemicals were used without further purification.

Synthesis of internally sulfonated polystyrene hollow sphere

50 g of light calcium carbonate was added into 100 mL of ethyl alcohol in a three-necked flask equipped with a mechanical stir. This mixture was homogenized for 30 min at 80 °C at a speed of 2000 rpm. Then 3.5 g of vinyl benzenesulfonic acid was added. The mixture continued to be stirred at a speed of 400 rpm at 80 °C for 2 h. Subsequently, 0.105 g of styrene, 0.105 g of divinyl benzene, and 0.07 g of BPO were added independently. After 2 h, this suspended mixture was cooled to room temperature, and the resulted solid particles were separated and collected by centrifugation. Then, they were washed with ethyl alcohol, and subsequently dried at 80 °C under vacuum for 12 h to obtain the polystyrene-coated calcium carbonate. The internally sulfonated polystyrene hollow spheres were obtained by removing calcium carbonate from polystyrene-coated calcium carbonate using hydrochloric acid (36% w/w). This polystyrene hollow spheres were further treated by repeatedly washing using distilled water until no hydrogen chloride was detected by AgNO₃ solution test. After being dried at 40 °C under vacuum for 12 h, 4.8 g of polystyrene hollow sphere with catalytic property was obtained. The scheme for the preparation of sulfonated polystyrene hollow sphere is shown in Fig. 1.

Characterization

Thermogravimetric analysis (TGA) was performed on a Netzsch STA409PC instrument (Bavaria, Germany) under a flowing nitrogen atmosphere at a scan rate of 20 °C min⁻¹ from room temperature to 1000 °C using α -Al₂O₃ as the standard material. TGA results reported were the average of a minimum of three determinations. Temperatures were reproducible to ± 3 °C, and the error bars on the fraction of nonvolatile material were $\pm 1\%$. Fourier-transform infrared (FT-IR) spectra of the samples were obtained using a WQF-200 spectrometer (Rayleigh, China) over a frequency range of 400–4000 cm⁻¹. The samples were mixed

Fig. 2 Typical TGA curve of polystyrene hollow sphere.

with KBr and pressed in the form of pellets for FT-IR analysis. Optical microscopic images of the samples were obtained using a N-180M microscope (Shanghai, China). The scanning electron microscopy (SEM) was performed on a FEI Nova NanoSEM 450 instrument (Hillsboro, America), and analyses were carried out on a Nova NanoSEM 450 equipped with an energy-dispersive X-ray analyzer. XPS measurements were carried out on a Shimadzu ESCA-3200 (Tokyo, Japan) using Al K α radiation. The catalyst was titrated with aqueous NaOH solution to determine the amount of catalytic -SO₃H group in it. In a typical procedure, 20 mg of the sample was suspended in 10 mL of 2 mol L⁻¹ aqueous NaCl solution for 24 h at room temperature, then this suspension was filtrated, and the resulting solution was titrated with 0.05 mol L⁻¹ aqueous NaOH solution.¹² The amount of catalytic -SO₃H group was calculated from the amount of NaOH used in the above titration reaction. The samples were quantitatively analyzed by HPLC with UV detector. The HPLC column was Phenomenex C18 (5 μ m, 250 mm \times 4.6 mm ID). The mobile phase was a mixture of methyl alcohol, phosphoric acid and H₂O in a volume ratio of 15 : 0.5 : 100 at a flow rate of 0.5

Fig. 1 The scheme for the preparation of sulfonated polystyrene hollow sphere.

Fig. 3 FT-IR spectra of polystyrene hollow sphere.

mL min⁻¹. The temperature of column was 30 °C and the wavelength was 280 nm.

The yield of gallic acid was calculated by the following equation:

$$Y = \frac{m_{GA}}{m_{TA} w_{TA}} \times 100\%$$

where Y is yield of gallic acid; m_{GA} is mass of gallic acid (determined by HPLC); m_{TA} is mass of tannic acid; w_{TA} is mass percentage of gallic acid to tannic acid after complete hydrolysis. w_{TA} was experimentally obtained as 80.3%.

Catalytic performance

The polystyrene hollow spheres were used as catalyst in the hydrolysis of tannic acid. In a typical reaction, 200 g of tannic acid and 600 mL of H₂O were added in a three-necked flask equipped with magnetic stirring bars and water-separation apparatus. After being stirred for 30 min, 7% w/w of catalyst (based on the mass of tannic acid) was added. The reaction temperature and time were set at 80 °C and 6 h, respectively. Then, the solution was cooled down. Reaction process was monitored using HPLC. The reaction temperature and time, the amount of polystyrene hollow sphere, the concentration of

tannic acid, and the recycling of catalyst were optimized and evaluated.

Results and discussion

Characterization of catalysts

TGA analysis. In this experiment, the thermal stability of polystyrene hollow sphere was evaluated using TGA, and the experimental results were shown in Fig. 2.

TGA analysis information includes the 5% weight loss temperature ($T_{5\%}$), the initial degradation temperature, the 50% weight loss temperature ($T_{50\%}$), the degradation temperature, and the char content (residual weight percent at 950 °C).¹³ Fig. 2 indicates that the samples began to lose weight at 300 °C, which is due to the thermal degradation of polystyrene hollow sphere. It is evident that the prepared polystyrene hollow sphere is thermally stable below 300 °C, which would be the upper limit temperature of the hydrolysis of tannic acid.

FT-IR analysis. FT-IR analysis was conducted to obtain the chemical structural information of the polystyrene hollow sphere. FT-IR spectra of polystyrene hollow sphere are shown in Fig. 3.

The characteristic absorption bands at 1190–1200 cm⁻¹ and 1020–1130 cm⁻¹ can be attributed to the asymmetric and symmetric stretching modes of O=S=O, respectively, and the absorption band at 573–629 cm⁻¹ can be attributed to the stretching mode of S–O.¹⁷ These above absorption bands are the evidence for the presence of –SO₃H in the prepared polystyrene hollow sphere. Furthermore, absorption bands at 1610–1623 cm⁻¹ and 2928–2932 cm⁻¹ are the evidences for the presence of phenyl groups. The absorption band at 3000–3460 cm⁻¹ indicates the presence of –OH group.¹⁸ All above evidences indicate that benzenesulfonic acid groups are present in the polystyrene hollow sphere.

Optical microscopic analysis. Optical microscope was used to obtain the particle sizes of light calcium carbonate, polystyrene-coated calcium carbonate, and polystyrene hollow sphere. The images are shown in Fig. 4.

Light calcium carbonates have irregular shapes and the particle sizes are in the range of 2–5 μm (Fig. 4A). The light calcium carbonate was coated with polystyrene to obtain polystyrene-coated calcium carbonate. The polystyrene-coated calcium carbonate has smooth surface and the sizes increase

Fig. 5 SEM image (A) and EDX analysis results (B) of polystyrene hollow sphere. Red box in (A) denotes the region analyzed by EDX (B).

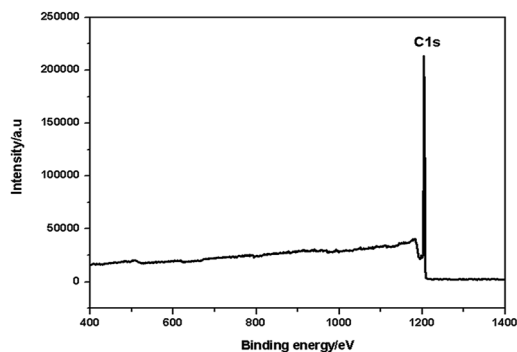

Fig. 6 XPS spectra of polystyrene hollow sphere.

Fig. 7 XPS spectra of polystyrene hollow sphere (magnified the XPS spectra near the positions where peaks of S occur).

to be in the range of 5–10 μm (Fig. 4B). Polystyrene-coated calcium carbonate was treated with hydrochloric acid solution to obtain polystyrene hollow sphere. Polystyrene-coated calcium carbonate and polystyrene hollow sphere have no significant difference in particle size and shape. The prepared polystyrene hollow sphere has a smooth surface with a size of 5–10 μm (Fig. 4C). From the perspective of catalyst, the size of polystyrene hollow sphere meets the size requirement of a high-performance catalyst.

SEM-EDX and XPS analyses. SEM-EDX and XPS analyses were performed on the polystyrene hollow sphere to determine the position of $-\text{SO}_3\text{H}$ groups. SEM-EDX is an X-ray technique used to reveal the elemental composition of materials. SEM-EDX analysis results consist of spectra showing peaks corresponding to the elements making up the true composition of the analyzed sample.¹⁹ SEM-EDX analysis of the polystyrene hollow sphere are shown in Fig. 5. There is no evidence for the presence of S element on the outer surface of polystyrene hollow sphere.

This polystyrene hollow sphere was also characterized by XPS to determine the elementary composition and valence state.

As shown in Fig. 6, the peak at binding energy of 1196.7 eV was assigned to C1s, confirming that the catalyst was composed of C. There is no peak at the binding energy of S, indicating no sulfonic group on the interior of the polystyrene hollow sphere.²⁰ We magnified the XPS spectra near the positions where peaks of S occur, but the peaks of S were still not found (see the following Fig. 7). Both XPS and SEM-EDX analysis results demonstrate that there is no element S present on the outer surface of the polystyrene hollow sphere. Considering the IR analysis results, we inferred that SO_3H groups should be on the inner surface of the polystyrene hollow sphere.

Application in the hydrolysis of tannic acid. Weighed amounts of tannic acid and H_2O (in a molar ratio of 1 : 3), as well as polystyrene hollow sphere (7% w/w, based on the mass of tannic acid) were added to a 500 mL three-necked round bottomed glass flask equipped with a water-cooled condenser and a magnetic stirrer. The temperature of the reaction mixture was controlled using a temperature controller with an accuracy of ± 0.5 $^\circ\text{C}$. The hydrolysis reaction of tannic acid (Fig. 8) was allowed to proceed for 0.5–6 h with vigorous stirring at the designed temperature. Then, the solution was cooled down. Subsequently, the amount of tannic acid in the reaction mixture was determined by HPLC.

The influences of (A) reaction time, (B) reaction temperature, (C) molar ratio of reactants, (D) loading of polystyrene hollow sphere and (E) number of recycles on the tannic acid hydrolysis were evaluated (Fig. 9).

Fig. 8 Hydrolysis of tannic acid using polystyrene hollow sphere as catalyst.

Fig. 9A shows the time course of yield of gallic acid at 80 °C, molar ratio of tannic acid to H₂O of 1 : 3, and polystyrene hollow sphere loading of 7% w/w (based on the mass of tannic acid). At first, the yield of gallic acid increased with the reaction time and reached 96.99% at 6 h of reaction. With further extension of reaction time, the yield remained almost unchanged and the yield at 10 h increased little compared with that at 6 h.

Fig. 9B shows the effect of reaction temperature on the yield of gallic acid. Reaction temperature was set in the range of 60–120 °C, while other reaction conditions were set as follows: molar ratio of tannic acid to H₂O of 1 : 3, reaction time of 6 h and polystyrene hollow sphere loading of 7% w/w. At 60 °C, the yield of gallic acid was 91.5%. As the temperature increased from 60 to 80 °C, the hydrolysis rate and the yield of gallic acid increased rapidly and significantly. As the temperature further increased from 110 to 120 °C, the yield of gallic acid slightly decreased. This indicates that gallic acid might be converted to pyrogalllic acid or other by-products. Fig. 9C shows the effect of the molar ratio of tannic acid to H₂O on the hydrolysis reaction. The molar ratio ranged from 1 : 1 to 1 : 6, at a reaction temperature of 80 °C, a reaction time of 6 h, polystyrene hollow sphere loading of 7% w/w. Fig. 8C indicates that the yield of gallic acid increases first and then decreases as the molar ratio changes from 1 : 1 to 1 : 6. The optimum molar ratio was found to be 1 : 3 in order to obtain the maximum yield of gallic acid. In the reaction system, water serves as both solvent and reactant. At first, with the increase in water content, more tannic acids are dissolved into water and the viscosity of the reaction system decreases, which is conducive to dispersion of reactants and enhancement of mass transfer. As a result, the yield of gallic acid increases. However, with further increase in water content, the concentration of tannic acid decreases, which results in decrease in yield of gallic acid. Fig. 9D shows the effect of polystyrene hollow sphere loading on the yield of tannic acid. The polystyrene hollow sphere loading was set at 3%, 5%, 7%, 10%, 15% and 20% w/w (based on the mass of tannic acid), respectively. Other reaction conditions included reaction

temperature of 80 °C, reaction time of 6 h, and molar ratio of tannic acid to H₂O of 1 : 3. All loadings of polystyrene hollow sphere could ensure a yield no lower than 90.5% (Fig. 9D). All above experimental results indicate a high catalytic performance of polystyrene hollow sphere.²¹ Note that the yield of gallic acid decreases when the polystyrene hollow sphere loading is above about 10%. This might be related to the calcium ions in polystyrene hollow sphere. As the polystyrene hollow sphere loading increases, the amount of calcium ions also increases. Gallic acid produced by hydrolysis of tannic acid might react with calcium ions to form by-products, thus affecting the yield of gallic acid. Considering both the reaction rate and the cost of polystyrene hollow sphere, 7% w/w was taken as the optimum polystyrene hollow sphere loading and used in most of the hydrolysis experiments.

Fig. 9E shows the effect of the number of recycle times on the activity and stability of polystyrene hollow sphere. After each cycle, the polystyrene hollow spheres were separated from the reaction mixture by decantation and then washed with water, followed by drying before the next run. Other reaction conditions included a reaction temperature of 80 °C, a reaction time of 6 h, a molar ratio of tannic acid to H₂O of 1 : 3, and polystyrene hollow sphere loading of 7% w/w.^{22–25} The experimental results indicate that the catalyst is stable enough to be recycled for many times. However, it is worth noting that the yield rate decreases slightly after the catalyst has been reused for 8 times. In order to find the reason for this trend, we performed XPS and SEM-EDX analyses of this catalyst before and after use (Fig. 10 and 11). Fig. 10 suggests that the intensity of the peak assigned to S decreases after the catalyst has been reused for 8 times. Fig. 11 shows that the peak corresponding to S shrinks after the catalyst has been reused for 8 times. It is thus inferred that the content of sulfonic groups in the catalyst decreases as the number of recycle times increases. This can lead to the degradation of the performance of catalyst and therefore decrease in the yield of gallic acid.

The hydrolysis of tannic acids in the presence of four different catalysts including polystyrene hollow sphere,

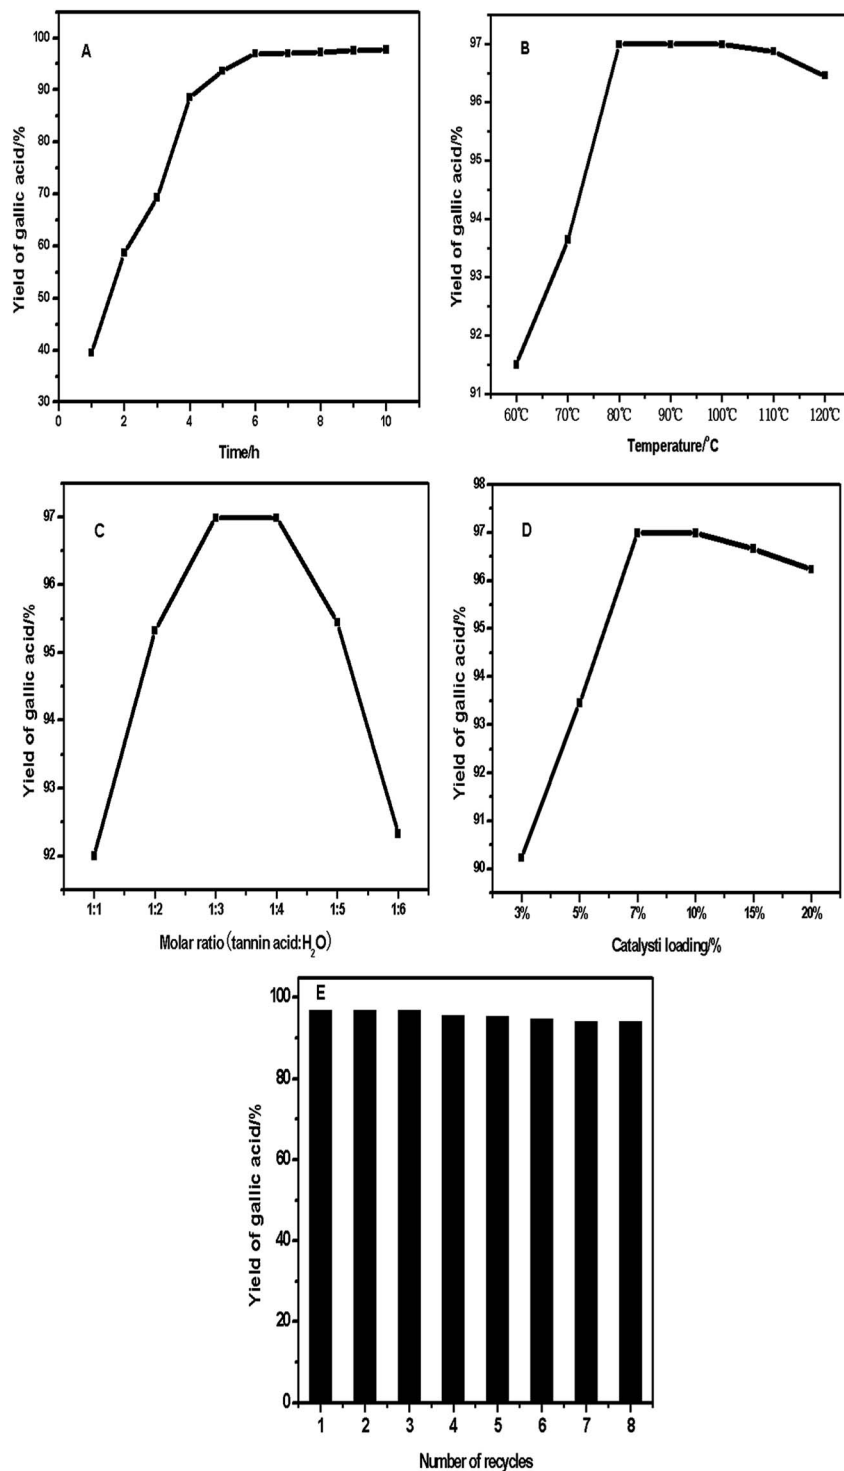

Fig. 9 Yield of gallic acid using polystyrene hollow sphere as catalyst (A) yield vs. reaction time; (B) yield vs. reaction temperature; (C) yield vs. molar ratio of reactants; (D) yield vs. catalyst loadings; (E) yield vs. number of recycles.

amberlite XAD-16, BC-SO₃H, PRPC-SO₃H were conducted to assess their catalytic activities under reaction conditions including a temperature of 80 °C, molar ratio of tannic acid to H₂O of 1 : 3, and polystyrene hollow sphere loading of 7% w/w (based on the mass of tannic acid). The experimental data are listed in Table 1.

The comparison experimental results indicate that the polystyrene hollow sphere has the highest performance as a catalyst for hydrolysis of tannic acid under the same reaction conditions with the same amount of sulfonic groups. The excellent catalytic performance of polystyrene hollow sphere might be attributed to its porous hollow structure, which is conducive to enhancing mass transfer.

Conclusions

This study provides a new strategy for the controllable synthesis of hollow structures with sulfonic groups on the inner surface. And this polystyrene hollow sphere has high performance as a green catalyst in the hydrolysis of tannic acid to obtain gallic acid. This polystyrene hollow sphere prepared in this study might be used as an excellent and prospective catalyst for the hydrolysis of high-molecule weight nature chemicals.
