Heterologous expression

ABSTRACT

The chemical diversity of terpenoids is typically established by terpene synthase-catalyzed cyclization and diversified by post-tailoring modifications. Fungal bifunctional terpene synthase (BFTS) associated P450 enzymes have shown significant catalytic potentials through the development of various new terpenoids with different biological activities. This study discovered the BFTS and its related gene cluster from the plant endophytic fungus *Didymosphaeria variabile* 17020. Heterologous expression of the BFTS in *Saccharomyces cerevisiae* resulted in the characterization of a major product diterpene variediene (1), along with two new minor products neovariediene and neoflexibilene. Further heterologous expression of the BFTS and one cytochrome P450 enzyme VndE (CYP6138B1) in *Aspergillus oryzae* NSAR1 led to the identification of seven norditerpenoids (19 carbons) with a structurally unique 5/5 bicyclic ring system. Interestingly, *in vivo* experiments suggested that the cyclized terpene variediene (1) was modified by VndE along with the endogenous enzymes from the host cell *A. oryzae* through serial chemical conversions, followed by multi-site hydroxylation via *A. oryzae* endogenous enzymes. Our work revealed that the two-enzymes biosynthetic system and host cell machinery could produce structurally unique terpenoids.

1. Introduction

Containing more than 80,000 members, terpenoids are the most structurally diverse family of natural products (NPs) [1,2], and are comprised of highly diverse biological activities that can be applied to many broad pharmaceutical uses [3]. The chemical diversity of terpenoids is generated by the combination of cyclization catalyzed by terpene synthases and a variety of post-cyclization tailoring modifications catalyzed by enzymes such as cytochrome P450 monooxygenases (P450s), methyltransferases, glycosyltransferases, and acetylases [4]. Among these, P450 enzymes, which are heme-containing proteins, catalyze many diverse reactions, including hydroxylation, heteroatom oxygenation, dealkylation, epoxidation, reduction, dehalogenation, and C–C bond formation or cleavage [5–7].

Fungi are a well-known rich source of terpenoids [4]. Among fungi-derived terpene synthases, bifunctional terpene synthases (BFTSs) have been discovered as unique types of chimeric enzymes containing a prenyltransferase (PT) domain and a terpene cyclase (TC) domain, and show the possibility of catalyzing the formation of structurally diversified di/esterterpenes [1,8,9]. Since 2007, a series of BFTS genes or BFTS-containing biosynthetic gene clusters (BGCs) have been obtained from various fungal species by using a combination of genome mining and heterologous expression in either *Aspergillus oryzae* (AO) or *Saccharomyces cerevisiae* (SC) [9–23]. Based on bioinformatics analysis and tandem heterologous expression, an anti-inflammatory 5/15 bicyclic sesterterpenoids was characterized from *Bipolaris sorokiniana*, and 5/6/7/3/5 pentacyclic sesterterpene synthases (FoFS and AtAS) from *Fusarium oxysporum* and *A. terreus* [18,19]. The FoFS catalyzed the

formation of fusoxypenes, which are enantiomeric with the precursor of the products of AtAS [18,19].

Two BFTSs, EvVS from *Emericella varicolor* [24] and AbVS from *A. brasiliensis* [25], which were both reported for the production of a tricyclic diterpene hydrocarbon variediene, have been characterized. The Dickschat group succeeded in expanding the enzymatic synthesis of variediene analogs by AbVS using dimethylallyl diphosphate (DMAPP) analogs and isopentenyl diphosphate (IPP) as the substrates [26]. However, the AbVS/EvVS-containing biosynthetic gene cluster (BGC) and their corresponding products have not yet been discovered. Here, we report the characterization of seven norditerpenoids with a rare 5/5 bicyclic ring system produced by a variediene synthase (DvVS) containing BGC from *Didymosphaeria variabile* 17020 (DV17020), through heterologous expression in *A. oryzae* NSAR1. Primary biosynthetic elucidation revealed that a single P450 enzyme (VndE) coupled with *A. oryzae* NSAR1 was responsible for producing these products from variediene (1).

2. Materials and methods

2.1. General experimental procedures

NMR spectra were acquired on an Agilent DD2 600 MHz spectrometer (600 MHz for ^1H NMR and 150 MHz for ^{13}C NMR, Santa Clara, CA, USA). NMR spectra were recorded in CDCl_3 (99.8 atom% enriched, Kanto), C_6D_6 (99.5 atom% enriched, Kanto), and pyridine- d_5 (99.8 atom% enriched, Kanto). Chemical shifts were reported in δ value based on residual signal of the solvent (CDCl_3 , δ_{H} 7.26 and δ_{C} 77.1), (C_6D_6 , δ_{H} 7.15 and δ_{C} 128.0) or (pyridine- d_5 , δ_{H} 8.74, 7.58, 7.22 and δ_{C} 149.0, 135.3, 123.3) as references. Data are reported as follows: chemical shift, multiplicity (s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet, br = broad), coupling constants (Hz), and integration. HR-EI-MS measurements were obtained on Waters GCT Premier mass spectrometer. A high-purity silica gel (Sigma 643) and 60 N silica gel (Kanto Chemicals) were used for column chromatography. LC-HR-MS(ESI) measurements were obtained on Thermo Q Exactive Orbitrap mass spectrometer coupling with a Shimadzu LC-20AD UPLC equipped with a Waters ACQUITY BEH C18 column (2.1 \times 100 mm, 1.7 μm particles). RP-HPLC was performed on an Agilent 1260 Series separation module with a diode array detector. Semipreparative HPLC was carried out using an ACE C18-PFP column (10 \times 250 mm, 5 μm , 4 mL/min), an ACE Excel 5C18 column (10 \times 250 mm, 5 μm , 4 mL/min), and a Cosmosil Cholesterol (10 \times 250 mm, 5 μm , 4 mL/min) column. GC-MS analyses were conducted with QP2010SE GC-MS (Shimadzu, Kyoto, Japan). Chirascan circular dichroism spectrometer was used to record the CD spectra of isolated compounds using MeOH as solvent. Optical rotation was measured using Rudolph Research Analytical Autopol V Automatic Polarimeter or JASCO P-2200 digital polarimeter. Biological reagents, chemicals, and media were purchased from standard commercial sources unless stated otherwise.

2.2. Strains and media

D. variabile 17020 was kindly provided by Prof. Hsiang from the University of Guelph (Ontario, Canada). Strains were all cultivated on 2% potato dextrose agar (PDA, Fisher Scientific) at 25 $^\circ\text{C}$ for 5 days and used as a source for the BFTS and post-modified genes cloning. *S. cerevisiae* BJ5464-NpgA (*MATa ura3-52 his3- Δ 200 leu2- Δ 1 trp1 pep4::HIS3 prb1- Δ 1.6R can1 GAL*) [27] was used for DvVS gene expression following standard recombinant DNA techniques. *A. oryzae* NSAR1 (*niaD*⁻, *sC*⁻, Δ *argB:adeA*⁻) [28] was used as the host for gene cluster expression. The *A. oryzae* transformants strain was grown in DPY medium at 30 $^\circ\text{C}$ and 200 rpm for 5 days.

2.3. Construction of expression plasmids

The genomic DNA was extracted using Rapid Fungi Genomic DNA Isolation Kit (Sangon Biotech). The five genes *orfA-C*, *vndD*, and *vndE* were amplified from the genomic DNA of *D. variabile* 17020 with primers shown in Table S1. PCR reactions were performed with the Q5[®] High-Fidelity DNA Polymerase (New England Biolabs). ClonExpress[®]II One Step Cloning Kit (Vazyme biotech) was used to construct expression plasmids by inserting PCR product into the appropriate restriction site of pUARA2 or pUSA2. The constructed plasmids are summarized in Table S2. The sequence of the five genes has been deposited in the National Center for Biotechnology Information (NCBI) with the accession number ON911568.

2.4. Transformation of *A. oryzae* and *S. cerevisiae*

The transformants AO-*vndD* (containing pUARA2-*vndD*) and AO-*orfABC/vndDE* (containing pUSA2-*orfABC* and pUARA2-*vndDE*) were constructed using protoplast polyethylene glycol method [29]. AO and AO-*vndD* are the abbreviations of *A. oryzae* and a transformant of *A. oryzae* harboring *vndD* gene, respectively. AO transformants listed in Table S2 were grown on MPY (Maltose Polypeptide Yeast extract medium; 3% maltose, 1% polypeptide, 0.5% yeast extract) medium containing 1% $(\text{NH}_4)_2\text{SO}_4$ and 0.01% adenine for 3–5 days at 30 $^\circ\text{C}$.

Complementary DNA (cDNA) of DvVS was used as a template of the PCR reactions for direct sequencing and subcloning each gene into the pXW55 vector using *SpeI* and *PmlI* restriction sites to afford pXW55-DvVS. The methods of cDNA synthesis and transformants SC-DvVS construction were the same as those in our previous study [19]. Yeast competent cell preparation and transformation were performed with Frozen-EZ Yeast Transformation II kit[™] (Zymo Research) according to the manufacturer's protocols. Yeast plasmids were prepared by Zymo-prep[™] Yeast Plasmid Miniprep kit (Zymo Research) and transformed into *Escherichia coli* strain DH10b for propagation.

2.5. Isolation and purification of diterpenes (1–3) and norditerpenoids (4–10) and their physicochemical properties

Mycelia of BFTS transformant SC-DvVS was inoculated into 250 mL Erlenmeyer flasks containing 100 mL YPD medium (Yeast extract Peptone Dextrose medium; 1% yeast extract, 2% peptone, 2% glucose) to prepare the seed culture, respectively. Fermentation was then carried out in 10 Erlenmeyer flasks (3000 mL) containing 1000 mL YPD medium at 30 $^\circ\text{C}$, 220 rpm for 3 days. Mycelia of the transformant AO-*orfABC/vndDE* was inoculated into 250 mL Erlenmeyer flasks containing 100 mL of MPY medium containing 0.1% $(\text{NH}_4)_2\text{SO}_4$ and 0.01% adenine to prepare the seed culture. Fermentation was then carried out in 125 aseptic bags (each containing 80 g rice and 120 mL water), and cultivation methods were the same as those in our previous research [19] incubated stationarily at 30 $^\circ\text{C}$ for 24 days.

Culture broth (10 L) of SC-DvVS was centrifuged at 5000 rpm for 10 min to gain the cell pellet 310 g, which was further extracted with acetone (1 L) at room temperature overnight and then concentrated *in vacuo*. The residues were extracted with ethyl acetate (500 mL \times 3). The combined organic layers were concentrated to yield a dark brown oil extract (230 mg), subjected to the silica gel column eluted by petroleum ether and afforded fractions G1–G9. G1 (3 mg) was further separated by semipreparative HPLC (100% ACN, 4 mL/min) over an ACE Excel 5C18 column to afford **3** (t_{R} = 27 min, 1.0 mg). G2 (20 mg) was further separated by semipreparative HPLC (100% ACN, 4 mL/min) over an ACE Excel 5C18 column to afford **1** (t_{R} = 21 min, 8.0 mg) and **2** (t_{R} = 24.5 min, 3.0 mg).

The fermentation products of transformant AO-*orfABC/vndDE* were extracted exhaustively with EtOAc and condensed *in vacuo*. The EtOAc layer (15 g after drying *in vacuo*) was fractionated by a Sephadex LH-20 column using MeOH as mobile phase to give nine sub-fractions

organism, which was required for the proteolytic cleavage of the transcription factor *pacC* [38]. Overall, *orfA* could be found in a few characterized fungal secondary metabolic pathways while *orfB* and *orfC* were not. Considering that these three genes were adjacent to the *DvVS* gene, we co-expressed them with *DvVS* and *vndE* to further verify their functionalities. As many fungal biosynthetic pathways are revealed through heterologous expression of *A. oryzae* [17,39–42], these genes were cloned into the expression vectors pUSA2 and pUARA2 for heterologous expression in *A. oryzae*. Two expression plasmids, pUSA2-*orfABC* and pUARA2-*vndDE*, were prepared and transformed into *A. oryzae*

Fig. 4. LC-HR-MS analysis of AO-*vndE* and AO fed with variediene (1) and varienordienoids (4 and 10). (A) LC-HR-MS profiles of 1 fed to AO-*vndE* (i) and AO (ii), chromatograms were extracted at m/z 337 + 321 + 319 + 303 [M - H]⁻. (B) LC-HR-MS profiles of 4 fed to AO-*vndE* (i), AO (ii), and blank medium (iii), chromatograms were extracted at m/z 337 + 321 [M - H]⁻. (C) LC-HR-MS profiles of 10 fed to AO-*vndE* (i), AO (ii), and blank medium (iii), chromatograms were extracted at m/z 337 + 321 + 319 + 303 [M - H]⁻.

to generate AO-*orfABC/vndDE*. This transformant was cultured in rice medium, or MPY medium supplemented with adenine.

Subsequent large-scaled fermentation and comparison of LC-MS metabolite profiles revealed that seven new peaks possessing similar UV spectra (Fig. S8B) were found in the AO-*orfABC/vndDE* fermentation extract (Fig. 2A). Isolation of these selected components with various chromatographic methods led to the characterization of seven previously unreported 5/5 membered bicyclic norditerpenoids, named varienordienoids A–G (4–10, respectively) (Fig. 2B). Their planar structures and relative configuration were determined by extensive spectroscopic experiments and DP4 analysis (Fig. S9–S16; Table S7–S17; Supplementary text). The absolute configurations of 4 (3*S*,4*R*,5*R*,11*S*), 5 (3*S*,4*S*,5*R*,7*R*,11*S*), 6 (3*S*,4*R*,5*R*,6*R*,11*S*), 7 (3*S*,4*S*,5*R*,7*S*), 8 (3*S*,4*R*,5*R*,6*R*), 9 (3*S*,4*R*,5*R*,10*S*), and 10 (3*S*,4*R*,5*R*), were established by TD-DFT based ECD computation (Fig. S17). The comprehensive structural elucidation of these compounds can be found in the Supplementary text. The unprecedented 5/5 bicyclic ring systems of these seven compounds are highly distinguishable from those 5/6 and 6/6 bicyclic ring systems observed in diterpenoids that have been previously characterized [43].

To characterize the functions of enzymes that produce 4–10, three *A. oryzae* transformants AO-*vndDE*, AO-*orfA/vndDE*, and AO-*orfAB/vndDE* were constructed (Fig. 3B and S18). The metabolites from these three *A. oryzae* transformants were analyzed by LC-MS experiments. Surprisingly, LC-MS analysis showed that the AO-*vndDE* cells could produce 4–10 (Fig. 3Bi). 4–10 were also detected in the AO-*orfA/vndDE* and AO-*orfAB/vndDE* samples (Fig. S18). These findings clearly suggested that the putative P450 enzyme VndE (CYP6138B1) [44] might contribute to the formation of all seven of these norditerpenoids, while OrfA–C were not. To identify the function of the P450 enzyme (VndE),

Scheme 1. Proposed varienordienoid biosynthetic pathway in *A. oryzae*. Colored dots marked the different positions of hydroxylation.

the BFTS and VndE were then heterologously expressed in *S. cerevisiae* RC01, which was introduced an integrated copy of the *A. terreus* cytochrome P450 reductase (CPR) gene into the genome of *S. cerevisiae* BJ5464-NpgA [45]. However, no product was found in these *S. cerevisiae* transformant extracts (data not shown), possibly due to the incompatible CPR.

It is of significance that the AO-*vndD* transformant did not produce any of these norditerpenes (Fig. 3Bii), which indicated that the P450 enzyme VndE was indeed involved in the biosynthesis of these varienordienoids. Speculations include theories that the complex transformation process from **1** to **4–10** might result from integrated catalysis involving the P450 VndE and endogenous *A. oryzae* enzyme(s), considering that unexpected oxidations on biosynthetic intermediates by *A. oryzae* have been reported recently, such as the heterologous production of prosolanapyrone [46] and 4-hydroxy-pyridines [47]. The unusual biotransformation process of these compounds in *A. oryzae* NSAR1 cells could require different reaction types and needs further extensive investigation to elucidate the corresponding mechanisms.

To verify that VndE is indispensable in the generation of **4–10**, feeding experiments were conducted using the AO and AO-*vndE* strains (transformant harboring *vndE* gene) with **1** as the substrate. Using HR-ESI-MS analysis, only **4** was successfully observed in the AO-*vndE* transformant but not in AO (Fig. 4A and S19), showing that VndE was vital for transforming **1** into norditerpenoids. However, no other predicted compounds (*i.e.* **5–10**) were detected, which might be attributed to the low conversion rate in this feeding experiment. Hence, **4** was directly used as the substrate in further feeding experiments, which resulted in the acquisition of compounds **5** and **6** in both AO and AO-*vndE* cells (Fig. 4B). Meanwhile, in the medium, **10** into **4** were found to spontaneous hydrate (Fig. 4Ciii). In addition, both AO and AO-*vndE* cells could transform **10** into **4–9** (Fig. 4Ci and 4Cii). These results suggested that the multi-site hydroxylation of norditerpenoids occurred in the presence of AO endogenous enzymes. Interestingly, the non-enzymatic conversion of **10** in the MPY medium generated a small quantity of **4**, which only accounted for 5% of the yield of this particular compound in AO cells supplemented with **10** (Fig. 4C and S20). In addition, **4** and its downstream products (**5** and **6**) displayed the 11*S* configuration, thus hinting that AO endogenous enzymes were involved in the stereoselective hydration at C-11.

A putative biosynthetic pathway was thus proposed that could account for the production of **4–10** in *A. oryzae* cells (Scheme 1). The cyclized terpene **1** was transformed to **10** based on the modifications by the VndE and AO endogenous enzymes through a series of chemical transformations, such as oxidation, decarboxylation, and C–C bond cleavage. The putative mechanism of the VndE-catalyzed reaction is shown in Fig. S21. Subsequent hydroxylation of **10** at the C-6, C-7, and C-10 positions formed compounds **7–9**, while hydration of **10** yielded **4**, which could be further oxidized into hydroxylated products **5** and **6**.

Nortriterpenoids have been discovered in other organisms [48,49], but most of their biosynthesis pathways are not yet fully understood.

In summary, a variadiene synthase DvVS was characterized from the plant endophytic fungus *D. variabile* 17020 and the major product diterpene variadiene (**1**) along with two new minor products (**2** and **3**) were identified. Unexpectedly, seven norditerpenoids (**4–10**) feature an unprecedented 5/5 bicyclic ring skeleton, generated by a simple two enzyme gene cluster comprised of one BFTS (DvVS) and a single P450 (VndE) in *A. oryzae* cells. VndE participated in the degradation processes (*i.e.* C–C bond cleavage, oxidation, and decarboxylation) of **1** but was not responsible for the multiple tailing hydroxylation. It is worth studying how the AO endogenous enzymes cooperate with VndE in the complicated modifications of **1**, in addition to which endogenous enzymes are responsible for the hydroxylation at every specific site. Furthermore, the OrfA–C adjacent to BFTS DvVS, which were predicted to be epoxide hydrolase, dehydrogenase, and unknown enzymes, might be cryptic. Further investigation on the activation of these genes and characterization of their corresponding products is ongoing.
