**Purpose:** Obesity is becoming one of the most common public health problems worldwide. In particular, central obesity which indicates abnormal fat accumulation in the abdominal regions is highly associated with the risk of getting cardiometabolic diseases and their progression to end stage diseases or death. However, in developing countries, including Ethiopia less attention has been given to analyze the magnitude and associated factors of it. Therefore, we aimed to determine the prevalence of central obesity and its associated factors among adults in urban areas of Northwest Ethiopia.

**Methods:** A cross-sectional study was conducted among 773 adults who lived in urban areas of Northwest Ethiopia from April 1 to May 30, 2019. Central obesity was assessed using both waist to hip ratio and waist circumference of the participants. Data were analyzed using STATA 14.0. The factors associated with central obesity were identified by binary logistic regression analyses using 95% confidence interval and the degree of association of the factors was measured using adjusted odds ratio (AOR). *P*-value <0.05 was used to declare statistical significance.

**Results:** The prevalence of central obesity with waist circumference and waist to hip ratio definition criteria was 37.6% and 35.7%, respectively. According to body mass index, about 26.26% and 10.29% of the study participants were overweight and obese, respectively. A one-year increase in age (AOR=1.05; 95%CI: 1.03–1.07), being female (AOR=9.62; 95%CI: 4.84–19.12) and eating of liquid oils (AOR=2.58; 95%CI: 1.71–3.90) were found to have statistically significant variables with central obesity.

**Conclusion:** The prevalence of central obesity was relatively high in comparison with similar studies. Thus, governmental and nongovernmental organizations that work in the health system as well as health professionals should focus on the preventive measure of central obesity to control its associated disorders at an early stage.

**Keywords:** central obesity, magnitude, associated factor, Northwest Ethiopia

## Introduction

Obesity is a complex disorder that is characterized by excess fat accumulation in the body.<sup>1</sup> Globally, it is becoming one of the major public health problems.<sup>2,3</sup> It is estimated that approximately one-third of the world's population are overweight or obese.<sup>4</sup> Although the prevalence of obesity varies across the world, it has an extensive impact on the life expectancy of the population.<sup>5</sup> In the USA, the prevalence of obesity and its associated disorders are steadily increasing in the last two decades.<sup>6</sup> According to published reports, a high proportion (up to 50%) of

the African population, especially those who are living in urban areas are under obesity or overweight, and it is expected that by 2025, the majority of obese individuals will be found in low and middle income countries.<sup>7,8</sup> As Ethiopia is one of these countries, the incidence and prevalence of general obesity is becoming extremely high.<sup>9–11</sup> The increment of sedentary lifestyle, nutritional transition, bad behavioral practice such as smoking and alcohol drinking, fewer physical activities, and urbanization are believed to be the major contributing factors for the global epidemic of obesity.<sup>12–14</sup> These factors along with obesity increase the prevalence and incidence rate of noncommunicable diseases both in developing and underdeveloping countries, which results in a double burden, especially in low and middle income countries, including Ethiopia.<sup>15,16</sup> Therefore, screening for obesity at an early stage is very important to overcome associated comorbidities and death, but addressing the site of excess fat accumulation in the body is believed to be a key determinant factor.

Based on the site of fat storage, obesity can be grouped into peripheral (gynoid), central (android), or a combination of both. The storage of excess fat in the buttocks, hips and thighs refers peripheral obesity. In central obesity, excess fat accumulates in the abdominal area which is a risky region for fat storage since vital organs and their bloodstream are located there.<sup>17,18</sup> Several reports have confirmed that central obesity is the most common form of obesity that associated with diverse health problems, such as diabetes mellitus, hypertension, cardiovascular diseases and several types of cancer.<sup>17,19–21</sup> In addition, the economic burden, including unemployment and early retirement from their job due to obesity-related complications is very high. Psychological and quality of life can also be compromised due to the development of obesity associated cardiometabolic problems.<sup>22,23</sup> Body mass index (BMI) is a common anthropometric measurement to indicate the obesity status or general adiposity of the individuals. However, it does not tell the area of excess fat accumulation and abdominal obesity-associated health problems.<sup>24–26</sup>

Besides, BMI does not differentiate weight gain due to excess fat accumulation or high muscle mass in the body.<sup>27</sup> Furthermore, central obesity (abdominal fat accumulation) alone can help to determine the risk of getting obesity-related disorders/cardiometabolic risks, but BMI without measuring visceral (abdominal) obesity does not show the exact risk of developing cardiometabolic risks. In some cases, centrally obese individuals may have normal

or low BMI values. For instance, in older individuals, their BMI may be normal or low due to the degeneration of their lean muscle mass, but the central obesity can be high because of body fat redistribution.<sup>28,29</sup> Thus, measurement of central obesity with waist circumference and/or waist-to-hip ratio is helpful to identify the risky types of fat storage in the body and its related complications.<sup>26,30</sup> Besides, central obesity is defined based on the International Diabetic Federation (IDF) and World Health Organization. Accordingly, in this study, central obesity was defined with Euroid driven cutoff point, as IDF suggested Sub-Saharan Africans (SSA) use it. However, to the best of our knowledge, empirical evidence on the prevalence of central obesity and its associated factors is scarce. Therefore, we aimed to determine the prevalence and associated factors of central/abdominal obesity among adults in urban areas of Northwest Ethiopia.

## Methods and Participants

### Study Design and Period

A community based cross-sectional study was conducted from April 1 to May 30, 2019 in urban areas of Northwest Ethiopia.

### Participants

All adults aged  $\geq 18$  years living in Gondar town and urban kebeles (the lowest administrative unit of Ethiopia or villages within each woreda (district)) of Dabat Health and Demographic Surveillance Site (HDSSs) Northwest Ethiopia were the source of population, whereas those adults living in Gondar town and urban kebeles of Dabat HDSSs for at least six months were the study population. Besides, all adults aged  $\geq 18$  years who lived there for at least six months and were available during the data collection period in Gondar town and urban kebeles of Dabat HDSSs were included, while pregnant and postpartum women, clinically confirmed edematous and abdominal distended adults by health professionals were excluded from the study. A total of 773 study participants were selected using multistage sampling technique. First, two study sites (Gondar town, and Dabat HDSS) were selected. Of these sites, all of the four urban kebeles of Dabat HDSS, and six of the total 23 kebeles of Gondar town with the lottery method were selected. Then, households were chosen through systematic random sampling technique by taking equal proportion of study participants from each of the selected kebeles. Finally, from each household,

one study participant was selected using the lottery method if more than one eligible individual resided in the house.

The sample size was determined using the formula for the estimation of a single population proportion with an assumption of 95% confidence interval, 5% margin of error, design effect of two and 50% expected proportion of central obesity. To compensate for the nonresponse rate, 10% of the determined sample size was added and the final sample size was 845.

## Data Collection Procedure

The data were collected using a pretested, semi-structured interviewer-administered questionnaire which was prepared based on World Health Organization stepwise survey tool for noncommunicable diseases (NCDs). The questionnaire took account of sociodemographic characteristics (age, sex, marital status, religion, educational status, occupation, and wealth index) and behavioral risks of NCDs, such as physical activity, dietary habit, smoking status, and alcohol consumption. WHO-identified risk factors of NCDs were expanded and optimized to suit local needs of the study areas. The questionnaire was first developed in English language then translated into local Amharic language for appropriateness and ease of approaching the study participants, and then re-translated back into English to check its consistency. The dietary and behavioral habits of the participants were assessed using a dichotomous yes and no questionnaire with expanded questions for those who answered yes about the type, duration and frequency of dietary, alcohol drinking and cigarette smoking habits. Then, alcohol drinking was defined as intake of any type of alcohol such as beer, wine, or locally prepared alcoholic beverages more than once per week for the last one year irrespective of the amount, and those who drink less than once per week for the last one year or never drink alcoholic products were taken as nondrinkers. Besides, smokers were defined as having a cigarette smoking practice within the last one year regardless of the amount, and those who never smoked in their lifetime or smokers prior to one year were taken as non-smokers. The physical activity of the respondents was categorized as vigorous, moderate, and poor physical activities based on the WHO and international physical activities analysis guidelines. A vigorous-intensity activity was defined as any activity that causes a large increase in breathing or heart rate (eg, running, carrying, or lifting heavy loads, digging or construction work) that continued for at least 30 min for a minimum of

three days per week. Moderate-intensity activity was defined as any activity that causes a small increase in breathing or heart rate (brisk walking or carrying light loads) that continued for at least 30 min for at least three days per week or five or more days of these activities for at least 20 min per day or  $\geq 3$  days of vigorous-intensity activity per week of at least 20 min per day. Low-level (sedentary) physical activity was defined as an individual having physical activity that is not meeting any of the abovementioned criteria.<sup>31</sup> The data was collected by trained public health officers and nurses under the supervision of the principal investigators.

## Anthropometric Measurements

Anthropometric measurements, such as weight, height, waist circumference and hip circumference were measured using standardized methods and adjusted equipment by professional health workers. Weight was measured in kilograms in bare feet without heavy outdoor clothing; height was measured in centimeters using a height board without shoes in an upright position. Consequently, BMI was calculated by dividing weight in kg with height in square meters,  $\text{kg}/\text{m}^2$ . Then, underweight, normal weight, overweight, and obesity were defined as a BMI  $\leq 18.5 \text{ kg}/\text{m}^2$ , between 18.5 and 24.9  $\text{kg}/\text{m}^2$ , between 24.9 and 30  $\text{kg}/\text{m}^2$  and  $\geq 30 \text{ kg}/\text{m}^2$ , respectively.<sup>32</sup> Waist circumference (WC) was measured in centimeters at the narrowest mid-point between the lower margin of the lowest palpable rib and the top of iliac crest with flexible plastic tape without heavy outdoor closing. Hip circumference was measured at the greatest posterior protuberance of the buttocks with a flexible plastic tape without heavy outdoor closing. Then, central obesity was determined by using both WHO and IDF definition criteria. Accordingly, central obesity is defined as waist to hip ratio of  $>0.90$  for males and  $>0.85$  for females or waist circumference  $>94$  cm for males and  $>80$  cm for females.<sup>33</sup>

## Data Quality Assurance

At each phase of the study, data quality control was performed. Initially, before two weeks of running the actual data, the questionnaire pretest was done on 39 volunteer participants at another urban area of Northwest Ethiopia having the same sociodemographic characteristics. Then, corrections and modifications were made accordingly. A one-day training was given for data collectors before running data collection. The training session covered the entire activities of the study, including objectives and

methodologies. Data collection was also under close supervision of the primary investigator and supervisors.

## Data Processing and Analysis

The data was entered, coded and cleaned using EpiInfo version 7, then exported to STATA version 14 for analysis. Consequently, descriptive statistics was done using mean, standard deviation, frequency and percentage. To identify factors associated with central obesity, both bivariable and multivariable binary logistic regression analysis were done. The variables in bivariable analysis with  $p$ -values  $\leq 0.2$  were fitted in the multivariable analysis. Then, the strength of association of variables with central obesity was determined by adjusted odds ratio (AOR) with a 95%CI. A  $p$ -value of  $<0.05$  was considered statistically significant in the multivariable model. Goodness of fit of the model was checked by the Hosmer–Lemeshow test. Finally, the results were interpreted and presented with tabulation and narration.

## Results

### General Characteristics of the Study Participants

Of the total 845 study participants, the data was collected from 773 study participants which gives a response rate of 91.5%. Of these, the majority, 477 (61.71%) were females and the mean age of the participants was  $37.6 \pm 15.4$ . Four hundred and eighty of the participants were married and the majority, 688 (89.12%) were Orthodox Christian. More than one third, 271 (35.06%) of the participants were educated up to college and above while most of the study participants, 334 (43.21%) were unemployed. Out of the total participants, only 15 (1.94%) of them were current cigarette smokers, and about 429 (55.57%) of the participants ever drank alcohol in their lifetime; of these, 392 (50.71%) drank alcohol in the last one year more than once per week. Regarding eating of fruit and vegetable diet, 43 (5.56%) and 76 (9.83%) of the participants had history of 5–7 times fruit and vegetable diet intake per week, respectively. Concerning the physical activity status of the participants, more than half of the participants, 404 (52.26%) practiced poor physical activity. Based on BMI, about 125 (26.26%) and 49 (10.29%) of the participants were overweight and obese, respectively (Table 1).

### Prevalence of Central Obesity

Based on waist to hip ratio and waist circumference definition criteria, the prevalence of central obesity was 35.7%

**Table 1** General Characteristics of the Study Participants Among Adults in Urban Areas of Northwest Ethiopia, 2020 (n=773)

| Characteristics                    | Number          | Percent |
|------------------------------------|-----------------|---------|
| Age (years)<br>Mean $\pm$ SD       | 37.6 $\pm$ 15.4 |         |
| Sex                                |                 |         |

**Abbreviation:** BMI; body mass index.

(95%CI: 32.4–39.2) and 37.6% (95%CI: 34.3–41.1), respectively. This condition was more prevalent in females with 86.6 (95%CI: 82.0–90.4) by waist to hip ratio and 85.9% (95%CI: 81.4–89.7) by waist circumference definition criteria (Table 2).

## Factors Associated with Central Obesity

The crude association of independent variables with outcome was done. Accordingly, age, sex, educational status, wealth index, type of oil eating and eating of vegetables and fruits were significantly associated factors with central obesity at  $p \leq 0.2$ . Of these variables, age, sex and type of oil eating were found to be statistically significant in multivariate analysis at  $p < 0.05$ . The odds of central obesity was increased by 5% for a unit increase of age in a year (AOR=1.05; 95%CI: 1.03–1.07). The odds of being centrally obese was 9.62 times higher among female study participants compared to their counterparts (AOR=9.62;

**Table 2** Prevalence of Central Obesity Based on WHO and IDF Criteria Among Adult Study Participants in Urban Areas of Northwest Ethiopia, 2020 (n=773)

| Central Obesity | Waist to Hip Ratio Criteria |                    | Waist Circumference Criteria |                    |
|-----------------|-----------------------------|--------------------|------------------------------|--------------------|
|                 | Number                      | Prevalence (95%CI) | Number                       | Prevalence (95%CI) |
| Total           | 276                         | 35.7 (32.3–39.2)   | 291                          | 37.6 (34.2–41.1)   |
| Male            | 37                          | 13.4 (9.6–18.0)    | 41                           | 14.1 (10.3–18.6)   |
| Female          | 239                         | 86.6 (82.0–90.4)   | 250                          | 85.9% (81.4–89.7)  |

95%CI: 4.84–19.12). The odds of having central obesity was 2.58 times higher in those participants eating liquid oil than those participants who are eating solid oils (AOR=2.58; 95%CI: 1.71–3.90) (Table 3).

## Discussion

The recent increase in obesity is becoming a major public health problem globally. Previously, it was known as a disease of the rich, but now it is increasing alarmingly in developing countries, including Ethiopia. It is in turn associated with the development of obesity-related diseases, which are too difficult to treat, especially in low and middle income countries. Therefore, early identification and screening of obesity, particularly the hidden type of obesity (central obesity) and its associated factors is believed to be effective to overcome the problem. In the current study, central obesity was found to be about 37.6% by waist circumference and 35.7% by waist to hip ratio definition criteria. A one-year increase in age (AOR=1.05; 95%CI: 1.03–1.07), being female (AOR=9.62; 95%CI: 4.84–19.12) and eating of liquid oils (AOR=2.58; 95%CI: 1.71–3.90) were found to be statistically significant variables with central obesity.

In this study, the prevalence of central obesity was 37.6% and 35.7% with waist circumference and waist to hip ratio definition criteria, respectively. This finding is in line with studies done in Brazil<sup>34</sup> and China.<sup>35</sup> However, our finding is lower than that of studies done in the USA,<sup>36</sup> Omani adults,<sup>37</sup> Eastern Sudan,<sup>38</sup> and Gondar, Ethiopia.<sup>39</sup> Conversely, the current finding is higher than that of the studies done in Northwest China,<sup>40</sup> Northern Iran,<sup>41</sup> India,<sup>42</sup> and Egypt.<sup>43</sup> These discrepancies may be due to the sociodemographic and ethnic background difference of the study participants.<sup>2,44</sup> In addition, the residence of the participants might also be one possible reason for the discrepancy in the study findings. For instance, individuals who lived in urban areas and developed countries are at higher risk of getting central obesity due to their overconsumption of processed and energy-dense foods more frequently than that of the rural residents.<sup>2,45</sup> As an individual consumes a high energy containing diet, the metabolic pathway shifts into anabolic process, including fat biosynthesis, and in turn leads to increment of fats in the circulatory system and the need to store it in order to maintain the metabolic activities.<sup>46,47</sup> Then, the excess fat will be accumulated in adipose tissue with unlimited fashion and will result in those individuals

**Table 3** Bivariate and Multivariable Logistic Regression Predicting the Odds of Central Obesity Among Adult Study Participants in Urban Areas of Northwest Ethiopia, 2020 (n=773)

| Characteristics                         | IDF Criteria |        |                  |                     |

**Abbreviations:** COR, crude odds ratio; AOR, adjusted odds ratio.

becoming centrally obese.<sup>47</sup> Furthermore, institutional-based studies may also contribute to higher prevalence of central obesity than that of community-based cross-sectional studies even within similar study settings. Thus, the previous study done in Gondar, which is a

similar study area with the present study, had found higher prevalence of central obesity than the present study because the study done by Janakiraman et al was focused only among University of Gondar Staff Members.<sup>39</sup>

Moreover, the cutoff point difference of waist circumference used in the studies might be another possible justification for the discrepancies. This is because of the cutoff points to determine central obesity across different ethnicities are slightly different due to the composition and shape of body difference between diverse ethnicities.<sup>44</sup> Scholars reported that the IDF central obesity definition criteria is the best cutoff points for SSA and Asian populations to show the higher threat of cardiometabolic risks.<sup>44,48,49</sup> Besides, the Adult Treatment Panel (ATP) III of the National Cholesterol Education Program definition criteria of central obesity, which takes a cutoff point of waist circumference  $\geq 102$  cm for men and  $\geq 88$  cm for women can be used for other ethnic background individuals.<sup>50,51</sup>

This study found that an increase in age was statistically associated with central obesity. This is supported by the studies done in Brazil,<sup>34</sup> Northwest China,<sup>40</sup> and Northern Iran,<sup>41</sup> which reported that participants with older age are associated with central obesity. Furthermore, other studies have been reported that being young is a statistically protective factor for the development of central obesity.<sup>42</sup> This might be due to the fact that the metabolic activity of the body gradually declines as we get older. Lower metabolic activity leads to more storage of fat in the body even with low intake of diet. In addition, as the people get older, the distribution and accumulation of fat shifts into the abdominal region and will have a chance to develop central obesity.<sup>52</sup>

In this study, being female was found to be associated with central obesity. This finding is consistent with the studies done in Brazil,<sup>34</sup> Oman,<sup>37</sup> Eastern Sudan,<sup>38</sup> Northern Iran,<sup>41</sup> and Southern China.<sup>53</sup> The exact molecular link between being female and central obesity is not clearly addressed yet. However, in this study the association of being female with central obesity may be due to their sedentary lifestyle and practice of less physical activity since most females who live in developing countries, including Ethiopia are housewives. Thus, they may spend more time at home with poor physical activities.<sup>54,55</sup> In addition, females may have poor awareness of central obesity since most females who are housewives are illiterate and unable to read leaflets posted in public areas and this may be a possible reason for the strong association of female sex with central obesity.<sup>56</sup> Furthermore, females naturally have a higher body fat percentage than males, which may contribute to having a higher body mass index of these respondents.<sup>57</sup> And it has been confirmed that the more generally obese individuals may increase the chance

of developing central obesity.<sup>36</sup> This is supported by other studies done in Southern China,<sup>53</sup> South Africa,<sup>58</sup> and Chile<sup>59</sup> which reported that being overweight and obese have a strong positive correlation with central obesity. Although BMI may not accurately differentiate weight gain due to high muscle mass or high fat accumulation in the body, the chance of getting central obesity is high in overweight and obese individuals compared with that of normal weight individuals.<sup>27</sup> However, we are not saying that centrally obese individuals may not have normal weight since individuals, especially elderly and young people, with normal weight might have central obesity.<sup>28,29,60</sup> As discussed earlier, central obesity is more dangerous than general or peripheral obesity for health. Therefore, screening of central obesity in the community should be focused in all individuals regardless of the BMI level.

The odds of having central obesity were 2.58 times higher among participants who ate liquid oils than those participants consuming solid oils. The ingestion of dietary types of oil in the development of obesity is still controversial. Many studies done in Africa and South Pacific populations revealed that there is no significant association between having dietary solid oil (coconut oil and palm oil) and the development of obesity.<sup>61–63</sup> Some other studies revealed that dietary solid oils are less likely to contribute to the development of obesity due to the high content of medium chain fatty acids, because these lipids are certainly oxidized and do not generally accumulate in the adipose tissue.<sup>64</sup> However, the dose of oil consumption matters in the development of obesity; as overeating of solid oil, especially those oils containing long and very long chain fatty acid promotes the initiation and progression of central obesity, while overeating of oils having polyunsaturated fatty acids rather protects the development of obesity, but polyunsaturated containing oils are too expensive and are not usually utilized as common dietary oils in developing countries, including Ethiopia.<sup>65,66</sup> Polyunsaturated fatty acids (linoleic and linolenic acids) are essential fatty acids by which we are totally dependent on the dietary sources. These fatty acids have antioxidant activity, and may in turn protect the initiation and progression of inflammation, which is believed to be a major risk factor for the development of central obesity.<sup>67</sup> Therefore, a strong association of liquid oil with central obesity in our study may be due to the type of unsaturated fatty acids found in the oil since most liquid oils found in developing countries may be made up of a

higher proportion of monounsaturated fatty acids. Thus, surplus monounsaturated fatty acids will be stored in the adipose tissue and will increase the waist circumference of the individuals.<sup>68</sup> Besides, a strong association of liquid oil with central obesity in our study may also be due to the fear of the participants of solid oils by which they assumed that liquid oils are protective against the development and progression of obesity. So that they may not be worried about the dose of liquid oils, whereas the individuals may believe that overeating of solid oil can contribute to the development of central obesity and may in turn critically restrict the amount of solid oil intake.<sup>65</sup>

## Strength and Limitation of the Study

This study detected the hidden type of obesity in the general population which did not get enough attention in Ethiopia and was the main strength of the study. The limitation of the study were cross-section based study design, and inability of measuring the dietary intakes of total energy and other nutrients.

## Conclusion

More than one-third of the study participants were found to be centrally obese, which is relatively high compared to respective studies. Increasing age, being female and eating of liquid oil were statistically associated with central obesity. Therefore, strategies should be designed to prevent the occurrence of central obesity in accordance with the risk groups. Besides, it is better to conduct community-based study with a large number of participants in Ethiopia to address the generalized magnitude of central obesity and its factors in the country.

## Data Sharing Statement

Data will be available from the corresponding author upon request.

## Ethics Approval and Consent to Participate

The study was conducted in accordance with the ethical principles of the Declaration of Helsinki. The ethical approval was obtained from the Ethical Review Committee of the College of Medicine and Health Sciences, University of Gondar with ethical approval number O/V/P/RCS/05/361/2018. Written informed consent

was taken from each study participant before running the study. Confidentiality was kept.

## Acknowledgments

The authors would like to acknowledge the study participants, data collectors and supervisors and University of Gondar.

## Author Contributions

All authors made substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; took part in drafting the article or revising it critically for important intellectual content; agreed to submit to the current journal; gave final approval of the version to be published; and agree to be accountable for all aspects of the work.

## Funding

No funding was received for this work.

## Disclosure

The authors report no conflicts of interest in this work.

## Diabetes, Metabolic Syndrome and Obesity: Targets and Therapy

Dovepress

### Publish your work in this journal

Diabetes, Metabolic Syndrome and Obesity: Targets and Therapy is an international, peer-reviewed open-access journal committed to the rapid publication of the latest laboratory and clinical findings in the fields of diabetes, metabolic syndrome and obesity research. Original research, review, case reports, hypothesis formation, expert opinion

and commentaries are all considered for publication. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
