Hydrocortisone, ascorbic acid, and thiamine (HAT) for sepsis and septic shock: a meta-analysis with sequential trial analysis

Weilan Na¹, Huili Shen², Yichu Li¹ and Dong Qu^{1*}

Abstract

Background: Sepsis is a primary global health threat and costs a lot, requiring effective and affordable treatments. We performed this meta-analysis to explore the treatment of hydrocortisone, ascorbic acid, and thiamine (HAT) in sepsis and septic shock.

Methods: We searched Ovid MEDLINE, Embase, and the Cochrane Central Register of Controlled Trials from inception to August 14, 2021. We included randomized controlled trials (RCTs) that evaluated the HAT treatments in sepsis and septic shock. The primary outcome was the change in SOFA score over the 72 h. The second outcomes were the hospital, and 28-/30-day mortality, the duration of vasopressors, PCT clearance, hospital length of stay (LOS), and ICU LOS. We performed a subgroup analysis and a trial sequential analysis (TSA). The Der Simonian–Laird random-effects models were used to report the pooled risk ratios (RR) or mean difference (MD) with confidence intervals (CI).

Results: Nine RCTs, enrolling 1427 patients of sepsis and septic shock treated with HAT (717) or only standard care (710), were included. There was a significant difference between the two groups in the change in SOFA score over the first 72 h (MD 0.65, 95% CI 0.30 to 1.00), the duration of vasopressors (MD -18.16, 95% CI -25.65 to -10.68) and the PCT clearance (MD 14.54, 95% CI 0.64 to 28.43). In addition, there was no significant difference in the hospital mortality (RR 1.07, 95% CI 0.85 to 1.34), the 28-/30-day mortality (RR 0.96, 95% CI 0.80 to 1.15), the hospital LOS (MD 0.78, 95% CI -0.30 to 1.86), and ICU LOS (MD 0.12, 95% CI -0.53 to 0.78).

Conclusions: The HAT combination improves the SOFA score in the first 72 h and reduces the duration of vasopressors in patients with sepsis. Given the minor mean difference of the change in SOFA score, the mortality benefit has not been observed.

Trial registration: PROSPERO, CRD42020203166.

Keywords: Sepsis, Meta-analysis, Hydrocortisone, Ascorbic acid, Thiamine

Introduction

Sepsis is a life-threatening organ dysfunction syndrome due to a dysregulated host response to infection [1]. It has been recognized as a primary health threat with high

morbidity and mortality, contributing to up to 5.3 million deaths worldwide each year and cost a lot [2]. Given the tremendous financial burden of sepsis, more effective but affordable treatments were required. A retrospective study, conducted by Marik et al. [3], first found that the combination of hydrocortisone, ascorbic acid, and thiamine (HAT) effectively reduced mortality and prevented organ dysfunction for sepsis and septic shock patients.

Hydrocortisone is considered as a typical adjuvant therapy for septic shock, based on the reversal of relative adrenal insufficiency. Low-dose hydrocortisone treatment may rapidly induce hemodynamic stabilization by reducing nitric oxide formation and can regulate the complex immune network in a widely ranging way [4]. Ascorbic acid, well known as Vitamin C, is an important antioxidant and an essential cofactor for biosynthesis and cell metabolism. In patients with sepsis and septic shock, there is a prevalent vitamin C deficiency trend upon admission to intensive care, resulting from increased oxidative stress [5]. Thiamine is referred to vitamin B1, an essential intermediate affecting pyruvate flux to the Krebs cycle. Thiamine deficiency has also been described in septic patients and led to increase lactate production via aerobic metabolism changes [6]. Polypharmacy act synergistically in multiple overlapping ways. This combination's biologic basis is the protective synergistic effect of hydrocortisone and vitamin C that ascorbic acid can restore glucocorticoid receptor function negatively affected by oxide [7]. Septic shock is associated with endothelial barrier dysfunction, which can be synergistically attenuated by hydrocortisone and vitamin C via the reversal of p53 and phosphorylated cofilin downregulation [8]. They also increase tight junctions between endothelial and epithelial cells, which preserves endothelial function and microcirculatory flow. Better yet, both are necessary for the synthesis of catecholamines and increase the sensitivity of vascular vasopressors [9]. In addition, thiamine, with glucocorticoids and vitamin C, can attenuate mitochondrial damage and promote mitochondrial function, which synergistically benefits a lot [10].

The HAT combination is simple, affordable, and theoretically beneficial for septic patients. However, as several RCTs showed conflicting results, the HAT therapy did not appear to reduce the mortality and was not supported for routine use [11–13]. A large retrospective cohort study of US adults with septic shock revealed that the use of HAT therapy increased significantly after Marik et al. [3] proposed the HAT combination, with more than 40% of the study hospitals using it [14]. This early adoption was due to high media attention rather than robust evidence of efficacy, which may carry unintentional risks. When considered in conjunction with recent studies, the combination seems to be a promising treatment, and this meta-analysis aimed to evaluate the effects of hydrocortisone, ascorbic acid, and thiamine given together in sepsis and septic shock.

Methods

Data sources and search strategies

The systematic review was performed following the Cochrane Handbook guidelines for Systematic Reviews of Interventions and the PRISMA statement [15, 16]. Trial sequential analysis (TSA) was used to increase the reliability of the meta-analysis and estimate the required information size [17]. The protocol was pre-registered on PROSPERO, ID: CRD42020203166. Ovid MEDLINE, Embase, and the Cochrane Central Register of Controlled Trials (CENTRAL) were searched using the search strategies (Appendix 1) on August 14, 2021. In addition, the reference lists of the included studies and relevant meta-analyses were checked.

Study selection

Inclusion criteria were as follow: patients (>18 years) with sepsis or septic shock; patients receiving HAT treatments in the intervention group; randomized controlled trials. As the HAT combination was first proposed in 2016, the definition of sepsis-3 was accepted. Considering the common use of glucocorticoids in sepsis and septic shock, we did not exclude the use in the control group and all types of glucocorticoids were included. There was no language restriction.

According to the inclusion criteria, two authors independently screened the titles and abstracts and then did full-text reviews of selected studies. Disagreements were resolved by consultation with a third member of the review team.

Data extraction

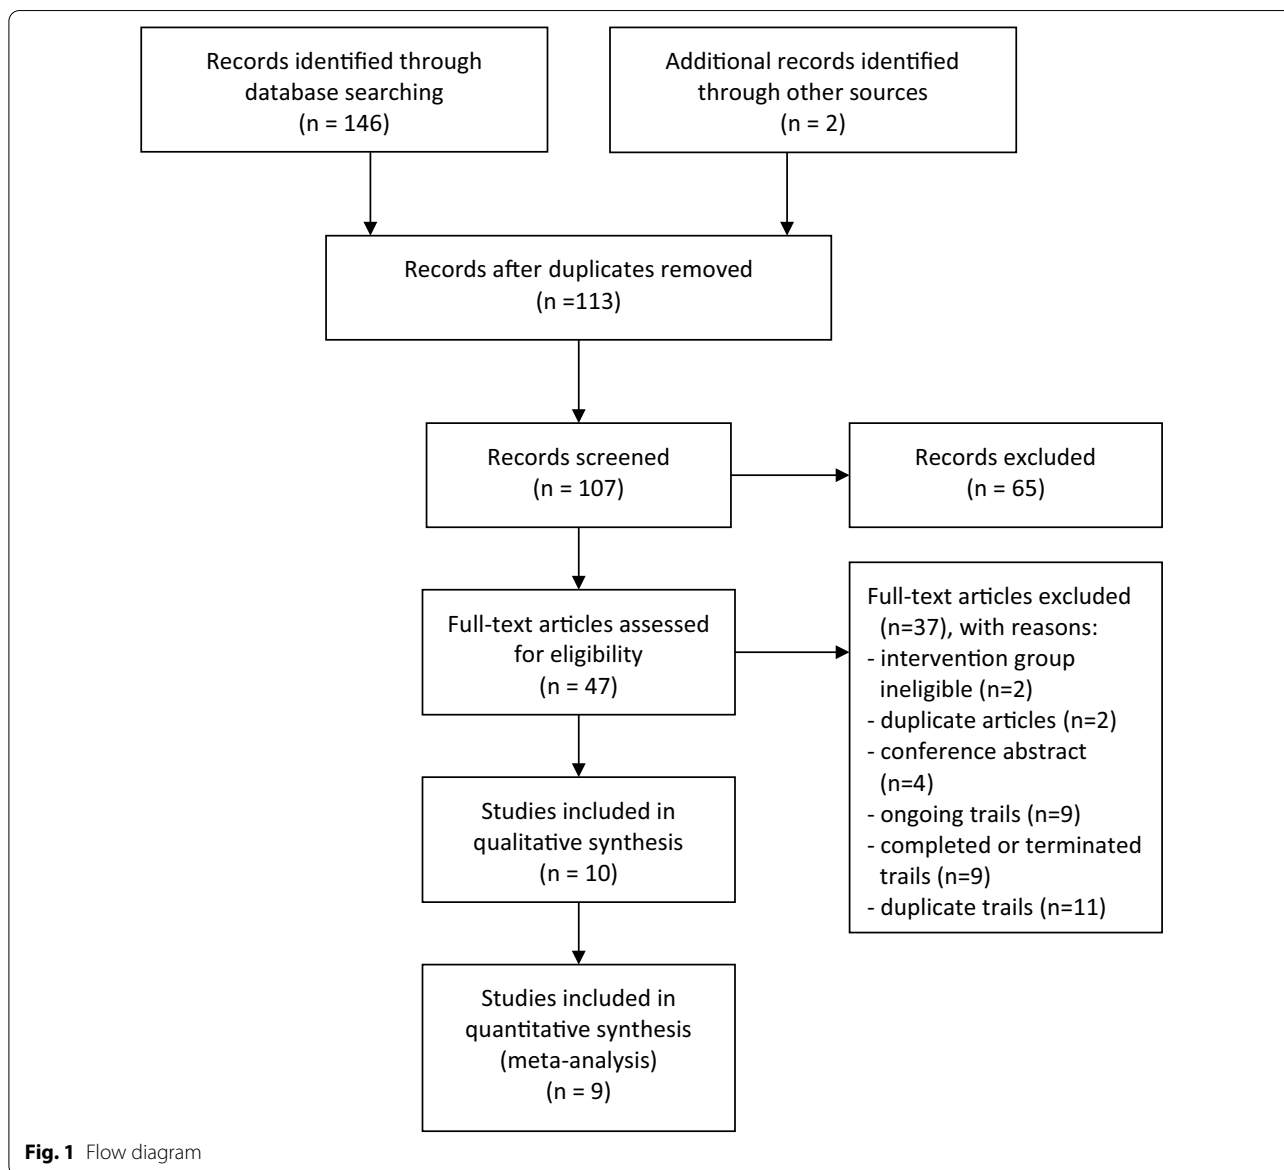

Two authors extracted data independently and consensus was reached. The data extracted included the following: authors, publication year, country, study design, number, inclusion and exclusion criteria, demographics, outcome measures and study results, independently.

Study endpoints

The primary outcome was the change in Sequential Organ Failure Assessment (SOFA) score over 72 h. Secondary outcomes were as follows: the hospital mortality, 28-/30-day mortality, the duration of vasopressors, procalcitonin (PCT) clearance, hospital length of stay (LOS), and ICU LOS.

Subgroup analysis and sensitivity analysis

For the subgroup analysis, septic shock was assessed as a subgroup. A sensitivity analysis was performed for

trials that excluded patients with renal failure at enrollment. For those analyses, the outcome was the change of SOFA score over 72 h.

Assessment risk of bias

The Cochrane Risk-of-Bias Tool was used to assess the risk of bias in the domains of selection, performance, detection, attrition, and reporting. Two authors completed the assessment independently, and disagreements were resolved by consensus or the third author.

Statistical analysis

Data were analyzed using Review Manager 5.3 and TSA 0.9.5.10 Beta program. We presented results as forest plots through the risk ratios (RRs) with 95% confidence intervals (CI) for dichotomous data. Forest plots using the mean difference (MD) with 95% CI were performed for continuous data. The heterogeneity was defined via I^2 statistic. An I^2 -value > 50% was considered heterogeneity. Random-effects model was used for all pooled analysis. If the value of P was less than 0.05, regarded as statistically significant. We also conducted a TSA to control random errors and calculate the required information size (RIS) based on a two-sided α of 0.05, β of 80%.

Results

Search results and study characteristics

The search retrieved 148 results up to August 14, 2021. After the elimination of duplicates, 113 studies were eligible based on the assessment of the title and abstract.

Then 47 trials were reviewed with the full text; 10 were included in the systematic review and 9 were included in the meta-analysis finally (Fig. 1). The excluded study did not contain the predefined outcomes [18]. One thousand four hundred and twenty seven patients with sepsis and septic shock were included in the meta-analysis (717 in the HAT treatment group and 710 in the control group). The characteristics of each trial were summarized in Table 1. The included studies differed in the application of glucocorticoids. In three studies [11–13], patients in the control group were only treated with the standard care for sepsis and septic shock, including broad-spectrum antibiotics, intravenous fluids, vasopressors, and mechanical ventilation. In another three studies [19–21], intensivists were allowed to order open-label corticosteroid therapy as deemed necessary. In three other studies [22–24], patients in the control group were routinely given low doses of glucocorticoids. In addition, the severity of sepsis was varied. Four trials focused on patients with sepsis including those with septic shock [11, 12, 19, 21] and the others only focused on patients with septic shock [13, 20, 22–24].

Outcomes

The forest plot of the primary outcomes was shown in Fig. 2. The change in SOFA score over 72 h was reported in six studies (588 in the HAT group and 575 in the control group). A significant reduction in SOFA score was revealed, with the use of HAT, and there was no significant heterogeneity (MD 0.65, 95% CI 0.30 to 1.00, P = 0.0003; I² = 0%, P_H = 0.58).

For the secondary outcomes, the pooled RR of hospital mortality and 28-/30-day mortality did not reach

the statistical significance (RR 1.07, 95% CI 0.85 to 1.34 and RR 0.96, 95% CI 0.80 to 1.15, respectively) (Fig. 3a and b). The pooled results of the duration of vasopressors revealed a significant reduction in the HAT treatment group, with no heterogeneity (MD – 18.16, 95% CI – 25.65 to – 10.68, P < 0.01; I² = 29%, P_H = 0.65; Fig. 3c). For the PCT clearance, there was statistical significance between two groups (MD 14.54, 95% CI 0.64 to 28.43; Fig. 3d). In addition, there were no significant differences in the hospital and ICU LOS between the two groups with pooled MD of 0.78 (95% CI – 0.30 to 1.86) and 0.12 (95% CI – 0.53 to 0.78), respectively (Fig. 3e and f).

For the subgroup analysis of septic shock, the result was presented in Fig. 4a. Four in seven studies were included and the HAT treatment showed a significant improvement in the SOFA score over 72 h (MD 0.67, 95% CI 0.17 to 1.18). For the sensitivity analysis, only two trials excluded the patients with renal failure at enrollment and there was also statistically significant (MD 1.03, 95% CI 0.07 to 1.99; Fig. 4b).

Trial sequential analysis results

TSA showed the adjusted pooled effect of the change in SOFA score over 72 h was 0.56 (95% CI 0.23 to 0.89) (Fig. 4c). The red cumulative z curve crossed the blue trial sequential boundary and the conventional boundary, indicating that the result was stable and statistically significant. In addition, the RIS of 1038 patients had been accrued, which indicated a sufficient number of studies.

Publication bias and risk of bias

The presence of publication bias for the primary outcome was tested and the funnel plot did not show the existence of publication bias via a visual inspection (Fig. 5a). For the risk of bias, the lack of blinding led to the performance bias and detection bias rated the highest (high risk of biases in 5/10 trials) (Fig. 5b).

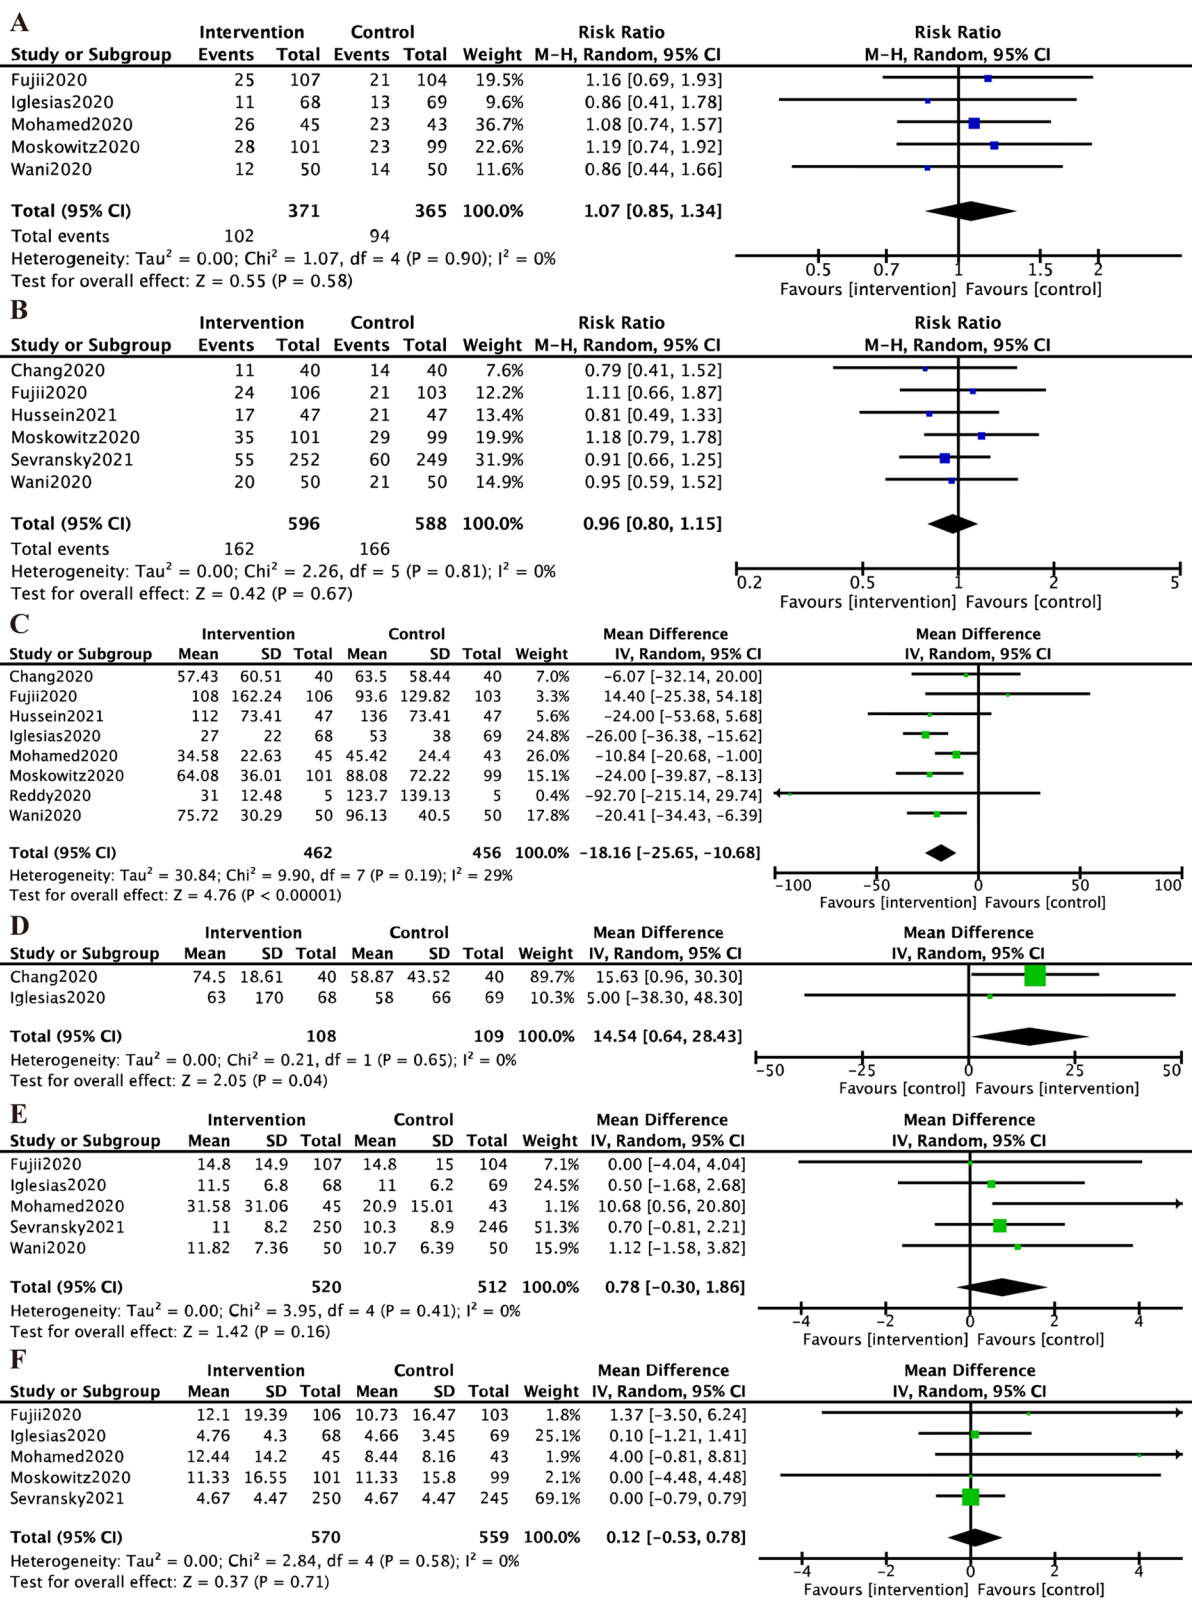

Fig. 3 Forest plots of the second outcomes. Legends Forest plots of the hospital mortality (a), 28-/30-day mortality (b), duration of vasopressors (hours) (c), procalcitonin clearance (d), hospital LOS (e), and ICU LOS (f) in the comparison between HAT treatment and control in sepsis and septic shock

Discussion

In this systematic review, the combination of hydrocortisone, ascorbic acid, and thiamine led to the reduction of SOFA score over 72 h, the duration of vasopressors and the improvement of PCT clearance. However, the HAT combination did not show benefit in the mortality, the duration of mechanical ventilation, and hospital or ICU LOS.

According to the Sepsis-3 clinical criteria, the diagnosis of sepsis has emphasized organ dysfunction which was represented by the increase of two points or more SOFA score. In addition, a change in the SOFA score was accepted by the European Medicines Agency as a surrogate marker of efficacy in exploratory trials of novel therapeutic agents in sepsis [25]. Moreover, organ dysfunction was associated with about 10% increase in mortality [26]. Therefore, we selected the change of SOFA score over the 72 h, rather than hospital mortality which was chosen in the PROSPERO registry, as the primary outcome. In this meta-analysis, there was a significant effect of the intervention on the change of SOFA score, but this did not be translated into a mortality benefit. First, hospital mortality is all-cause mortality and is influenced by many factors, such as comorbidities. Most included studies did not exclude the patients with a terminal end-stage disease or with imminent death, which may underestimate the therapeutic effect. In addition, the pooled effect (MD 0.65, 95% CI 0.30 to 1.00) was so minor and did not achieve the minimal clinically important difference, which was set as a 2-point difference [1, 13]. However, caution should be paid to the interpretation of the statistical results. It is valid only if the SOFA change is clinically relevant. The SOFA score focused on the early recovery of organ function and was assessed only if the patients remained in the ICU on the third day. Considering of the potential endpoints, such as death or recovery leading to early discharge from ICU, which increased the bias of competing risk [22]. Although the pooled effect of both meta-analysis and TSA supported the reliability and stability, the mean difference was small and we should still be cautious to evaluate the effect of HAT combination on the organ function.

Numerous retrospective studies showed a conflicting result on the mortality benefits, but the HAT combination did not provide significant survival benefits in this

meta-analysis. In the study of Wald et al. [27], the HAT combination was found to be associated with lower mortality in pediatric septic shock, and the improvement seemed to be primarily associated with reduced early deaths. In addition, Marik et al. [3] found that the early use of the HAT combination appeared to significantly affect patients' hospital mortality with sepsis and septic shock. According to clinical pharmacologic knowledge and pathophysiological mechanisms, we speculated that the early use of the HAT combination may make sense for patients at different sepsis stages. Noteworthy, the HYVCTTSSS trial, conducted by Chang et al. [12], showed that the HAT group got a better therapeutic effect than the control group in the subgroup, where patients were diagnosed with sepsis within 48 h, reflected mainly in the improvement of mortality. Hence, there is reason to believe that early treatment can lead to higher survival rates.

Theoretically, glucocorticoids and vitamin C have the ability to synergistically increase the sensitivity of vasopressors, which was also reflected in the results of this meta-analysis. In the HAT group, the duration of vasopressors was significantly reduced. Early liberation from vasopressor therapy means early recovery from septic shock. Although it could provide a more stable hemodynamic basis for subsequent treatment, the infectious source control remains the key for the mortality. The prognostic value of serum PCT in septic patients has been widely investigated and PCT non-clearance are strongly associated with all-cause mortality [28, 29]. Although there was statistically significant, caution should be exercised when interpreting the unstable results. In the ViCTOR Trial [20], the hospital LOS was significantly higher in the HAT group. However, after adjusting for outliers, the average LOS between the study groups did not significantly differ, which was consistent with the pooled effect of this meta-analysis.

Two meta-analyses regarding the effects of HAT therapy were published recently. Both Zayed et al. [30] and Somagutta et al. [31] concluded that HAT therapy significantly improved the SOFA score but appeared not to have significant benefits in the mortality, which was consistent with the results of this meta-analysis with a larger sample size. However, in our meta-analysis, instead of focusing on mortality, we set the change in SOFA score

(See figure on next page.)

Fig. 4 Subgroup analysis, sensitivity analysis and TSA of the primary outcome. Legends: **a** Forest plots of the subgroup analysis for the change in SOFA score over the first 72 h. Septic shock was assessed as a subgroup. **b** Forest plots of the sensitivity analysis for the change in SOFA score over the first 72 h. Trials that excluded patients with renal failure at enrollment was assessed. **c** Trial sequential analysis for the change in SOFA score over the first 72 h. The blue cumulative z curve crossed the conventional monitoring boundary and the red trial sequential boundary for benefit (the pooled effect, 0.56; 95% CI 0.23–0.89; $I^2 = 0\%$). The required information size (RIS) was 1038 (a two-sided α of 0.05, β of 80%)

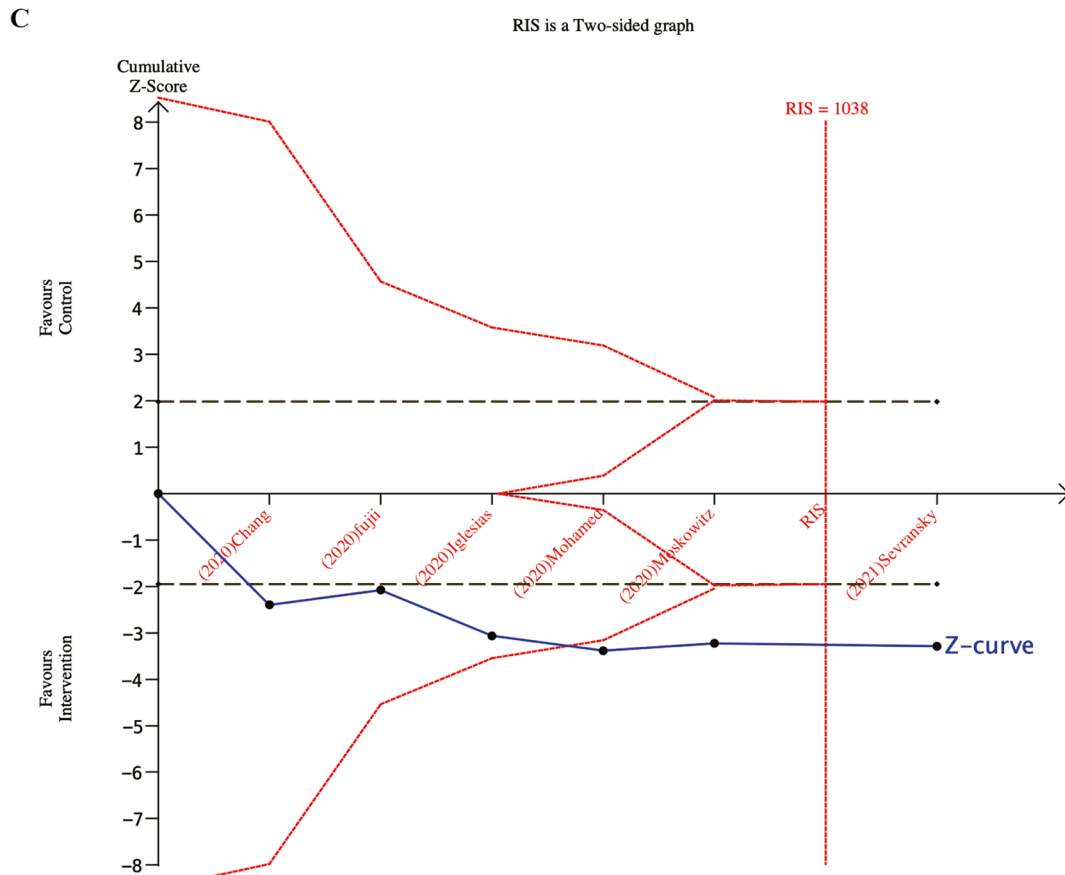

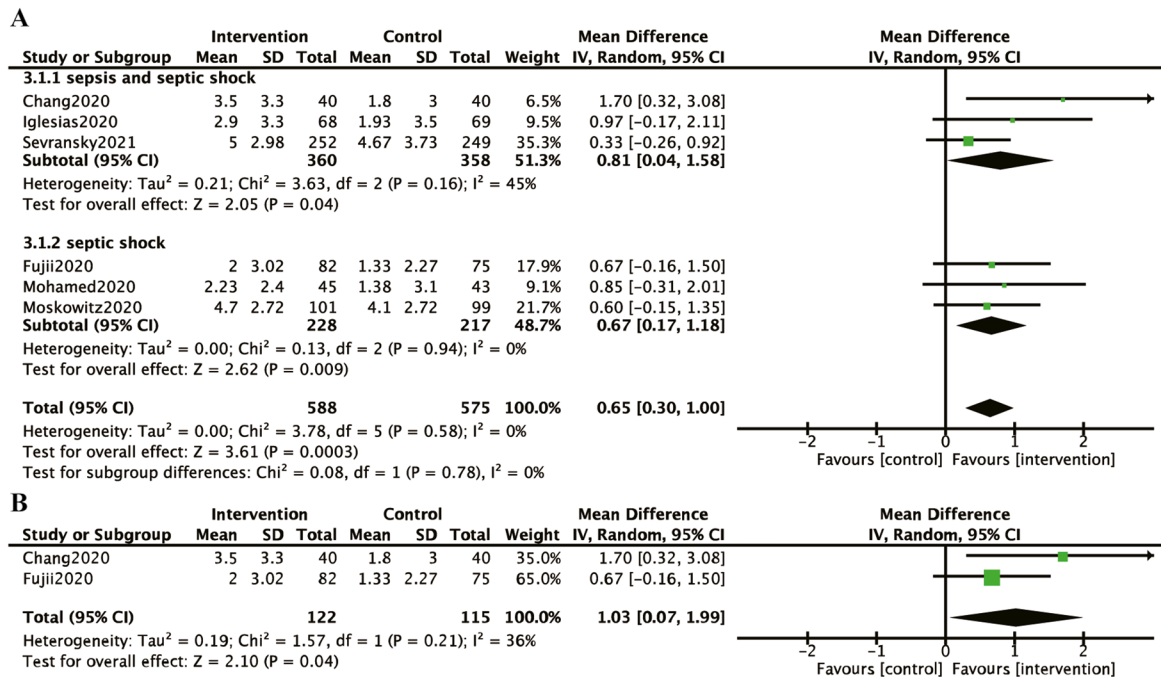

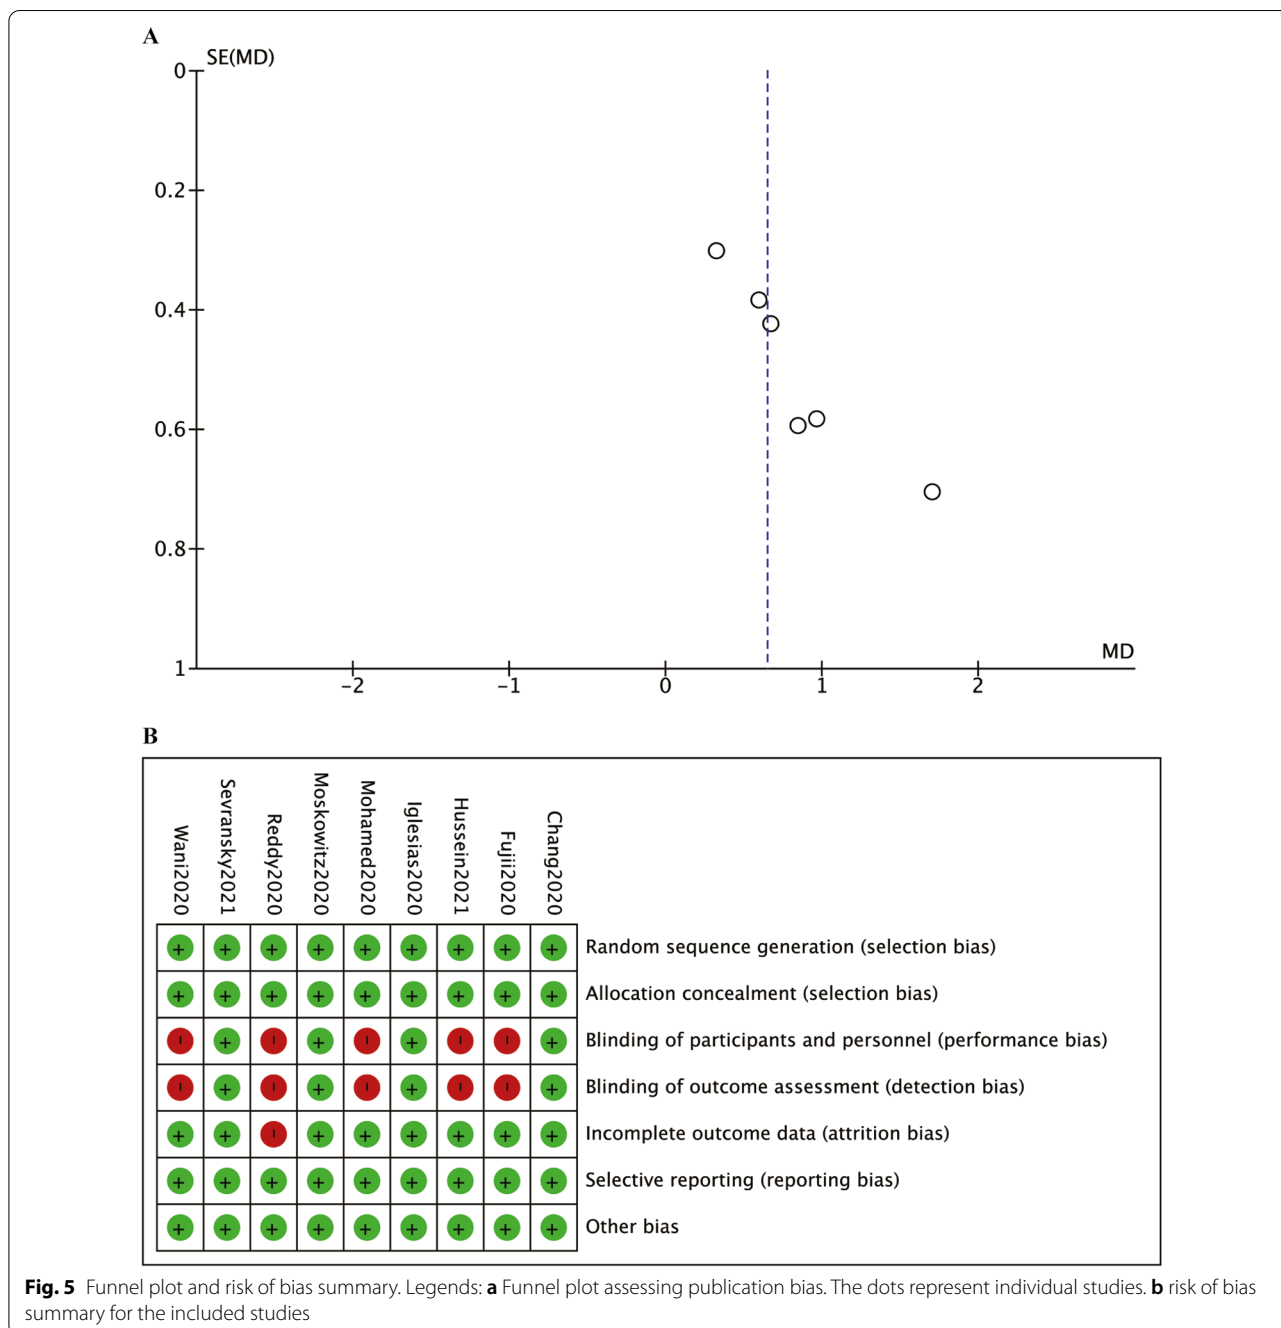

Fig. 4 (See legend on previous page.)

as the primary outcome. This is the first meta-analysis that placed importance on the effects of HAT therapy on organ function. We also discussed the pathophysiologic basis and the synergistic effects for these three drugs. Moreover, we conducted TSA, subgroup analysis and sensitivity analysis to enhance methodological quality. The VICTAS trial was a large multicenter RCT, published by Sevransky et al. [21] on JAMA, which enrolled 501 patients from 43 hospital in America. With inclusion of

the VICTAS trial, the results of TSA showed that the RIS was reached, and the statistical results were significant and stable. In addition, this meta-analysis is the largest at present, with nine RCTs included.

Several limitations should also be considered. First, five trials of all included were lack of blinding, which is the association with underestimation of adverse effects. Moreover, this review did not focus on side effects. The HYVCTTSSS trial was terminated at interim analysis due

to the significant incidence of hypernatremia in the HAT group [12]. Intravenous high dose of vitamin C in patients with renal failure was likely to increase oxalate, which eventually metabolized through kidneys, put their kidneys under stress [32]. Nevertheless, those could be managed in ICU. Finally, this review did not conduct more subgroup analysis. Optimal dosing time, dosage, and the administration of glucocorticoid should be considered to guide clinical practice.

Conclusions

The HAT combination improves the SOFA score in the first 72 h and reduces the duration of vasopressors in patients with sepsis. Given the minor mean difference of the change in the SOFA score, the mortality benefit has not been observed.

Ready to submit your research? Choose BMC and benefit from:

- fast, convenient online submission
- thorough peer review by experienced researchers in your field
- rapid publication on acceptance
- support for research data, including large and complex data types
- gold Open Access which fosters wider collaboration and increased citations
- maximum visibility for your research: over 100M website views per year

At BMC, research is always in progress.
