Results. The overall reduction of IPD cases by serotypes included in PCV13 was 88% for children and 67% in adults with a constant increase of IPD cases by serotype 8 in adults since 2015. In children, serotypes 24F (12%), 8 (10%) and 3 (9%) were the most frequent in 2019 whereas in adults, serotypes 3 and 8 accounted for 37% of IPD cases. IPD cases in adults by additional serotypes covered by the 23-valent polysac-charide vaccine (PPV23) have risen constantly within the years, increasing from 19% in 2009 to 52% in 2019. IPD cases by Non-vaccine types in adults (not covered by PCV13 or PPV23) show a moderate increase from 14% in 2009 to 24% in 2019.

Conclusion. Emerging serotypes are observed in Spain with the rise of serotype 24F in children and 8 in adults as a worrisome event.

1516. Outbreak of SARS-CoV-2 among Migrant Farm Workers in North Florida Khalil Nasser, MD¹; Vanneza Tabon, BS¹; Dushyantha Jayaweera, MD, mrcog(uk), face²; Tiffany Elias, BS¹; Kavya Jasti, BS¹; Raja Talati, MD MBA MSc FACP¹; Moti Ramgopal, MD FIDSA¹; Midway Specialty Care Centers, Fort Pierce, Florida; ²University of Miami, Miami, Florida

Session: P-68. Respiratory Infections - Viral

Background. Migrant farmworkers have been identified as a vulnerable population for Severe Acute Respiratory Syndrome Novel Coronavirus-2 infection (SARS-CoV-2). The objectives of this study were to detect the SARS-CoV-2 infection (COV19) status among 262 migrant farmworkers in North Florida.

Methods. This is a retrospective analysis of the information gathered from migrant workers referred by the Florida Dept. of Health for evaluation. Due to the urgency of returning to Mexico, subjects with which COV19 was detected were reevaluated for detailed medical history. Therefore, subjects that tested negative were later released following CDC guidelines. COV19 status was determined using an RNA qualitative nucleic acid amplification test (NAAT) from nasopharyngeal swabs collected over a three-day period. Variables collected include demography, symptoms, temperature, comorbidities, medication use, and vaccine status. Statistical significance for categorical variables was assessed using χ^2 test or Fisher's exact test where appropriate. Remaining variables were assessed using basic descriptive analysis.

Results. From the 262 subjects tested, 6 missed the follow up visit and data was unavailable. All were Mexican males, age 18-67 years, with positivity rate of 35.1%. Among the 92 (+) subjects, the average age was 34.1 years and 34.5 among the 164 (-) subjects, (p=< 0.77). The symptoms and temperatures are in Table 1. Three of the 92 COV19 (+) subjects were hospitalized, non-ICU and made an uneventful recovery. 59.8% of COV19 (+) subjects were asymptomatic. Among the 92 (+) subjects, 20.7% reported using acetaminophen within the last 60 days. The most common reported comorbidity was being a former smoker or current smoker, at 12.0% and 4.3% respectively.

| | Migrant Workers (n=92) SARS-CoV-2 (+) | Migrant Workers (n=164) SARS-CoV-2 (-) | P value |
|-------------------------|---|--|---------|
| Age, years | | | <0.77 |
| Mean (SD) | 34.1 (9.04) | 34.5 (10.44) | |

| Vaccination Status | 84 (91.3%) | N/A | 1.1 |
| Unvaccinated | 11 (13.1%) | N/A | |
| Mono-Vaccinated | 48 (57.1%) | N/A | |
| Dual-Vaccinated | 25 (29.8%) | N/A | |

 ${\it Conclusion.}$ The COVID-19 pandemic has highlighted migrant workers as a vulnerable population with astronomical COV19 rates, compared to others in FL

(14/100,000). They are impoverished, uneducated, undocumented, uninsured and employed to perform arduous physical labor and it is essential to provide basic health-care to prevent the spread of COV19.

1517. Outcomes of Influenza Infection among Vaccinated and Un-Vaccinated Patients presenting to a Suburban hospital in Perth, Western Australia (WA), 2019 Southern Hemisphere Influenza Season

Ohide Otome, MBChB FRACP¹; Ed Fysh, MBBS PhD²; Afsin Shariar, MBBS³; Andrew Chin Hock Yuan, MBBS³; Phoebe Brownell, MBBS⁴; Aysha Abu-Sharifa, MD³; Claire Bailey, MBBS³; Victoria Hall, MD³; Aiofe Tarrant Courtney, MBBS³; Marese O'Reilly, MBBS³; ¹Infectious Diseases / Microbiology, Midland, Western Australia, Australia; ²SJG Mildand Hospital, Perth, Western Australia, Australia; ³SJG Midland Hospital, Perth, Western Australia, 4STG Midland hospital, Perth, Western Australia, Australia, Australia, Australia, Australia, Perth, Western Australia, Australia

Session: P-68. Respiratory Infections - Viral

Background. Influenza season started in April, earlier than any previous season. WA immunization registry showed a higher than average vaccine uptake. By October 22,770 cases and 80 influenza related deaths were recorded (in 2018: 3,679 cases and 13 deaths). We aimed to characterize clinical presentation and outcomes of laboratory confirmed Influenza, comparing vaccinated with unvaccinated controls. Hypothesis; vaccination would result in less severe disease and better outcomes. Primary objective: length of stay (LOS); Secondary objective: prevalence of severe respiratory illness, ICU admission and death.

Methods. Retrospective study, April to October 2019. Eligible patients had a telephone-based questionnaire for clinical and immunization data verification. Excluded; < 18 years; deceased; dementia; nursing home and unable to consent. Continuous and categorical data of cases (vaccinated) and controls (unvaccinated) were compared using Mann-Whitney U test (non parametric), student t-test (parametric). Correlation and multilinear regression analyses were undertaken to determine the effects of vaccination status and identified confounders on the primary outcome. Based on previous average LOS (5 days, SD 1.5) the sample required to detect a difference of 1 day with 80% power was 70 patients. This study was approved by the SJGHC HREC.

Results. Of 163 eligible, 83 completed the questionnaire. 8 were excluded. 75 underwent analysis (50 vaccinated and 25 unvaccinated). Median age was 75 (23-83) and 63 (33-70) respectively (p < 0.01). 76% vs 48% reported >1 comorbidity (p = 0.02). 10% vs 0% were admitted to ICU (p = 0.16). Higher vaccination uptake was seen in older patients and those with comorbid conditions. There was a strong correlation (Spearman r= 0.54 (0.34 to 0.68, p < 0.001) between age and length of stay, but none was found between comorbidity or vaccination and length of stay. Neither age (p > 0.05), comorbidity status (yes/no; p=0.99), vaccination status (p=0.61) nor any combination of these variables were significantly associated with a dichotomised outcome of acute hospital stay > 3 days.

Conclusion. Vaccination with the 2019 influenza vaccine had no significant effect on hospital length of stay, mortality or critical care requirement in patients admitted to hospital with influenza.

1518. Real-World Comparative Effectiveness of Baloxavir Marboxil versus Oseltamivir on Influenza-Related Complication and Resource Utilization

Eddie Neuberger, PharmD¹; Chris Wallick, PharmD, MS²; Devika Chawla, PhD MSPH²; Rita de Cassia Castro, MD²; ¹Genentech, Inc, South San Francisco, California; ²Genentech, Inc., South San Francisco, CA

Session: P-68. Respiratory Infections - Viral

Background. In the 2018-19 season, there were an estimated 490,500 hospitalizations and 24,000 deaths from influenza in the US. Understanding how antiviral use affects rates and severity of complications is crucial to inform clinical practice. The objective of this study was to compare the frequency and costs of complications in influenza patients treated with baloxavir compared with oseltamivir-treated patients. This is one of the first analyses to examine comparative effectiveness of baloxavir in a real-world setting.

Methods. This retrospective cohort study used IBM MarketScan US administrative claims data from the 2018–19 influenza season. Patients were required to have an outpatient visit for influenza followed by a prescription for baloxavir or oseltamivir within 2 days. Baloxavir- and oseltamivir-treated patients were propensity score matched based on key baseline clinical and demographic characteristics. All-cause, all respiratory-related, and select respiratory-related (infection, asthma, and COPD) HRU in the 15 and 30 days following prescription fill were assessed using chi-square and Fisher's exact tests for categorical measures and Wilcoxon signed-rank tests for counts and costs.

Results. We included 5,080 baloxavir-treated patients and 10,160 matched oseltamivir-treated patients in the analysis. Statistically significantly lower HRU was associated with baloxavir compared with oseltamivir therapy (15-day: respiratory-related ED visits, select respiratory-related ED visits and outpatient visits; 30-day: all-cause hospitalization, respiratory-related ED visits, select respiratory-related ED visits and outpatient visits; (**Table 1**). Similarly, associated costs were generally lower in the baloxavir-treated group. Baloxavir-treated patients had lower mean per-patient all-cause 15-day costs (ED visits: \$30 [95% CI: \$21-\$39] vs \$42 [95% CI: \$32-\$51]; hospitalizations: \$31 [95% CI: \$55-\$79]; hospitalizations: \$47 [95% CI: \$15-\$80] vs \$119 [95% CI: \$78-\$161]).
