The title compound, $C_{15}H_{14}Br_2O_4$ [systematic name: *rac*-(9*S*,10*R*)-3,9-dibromo-10-methoxy-8,8-dimethyl-9,10-dihydropyrano[2,3-*h*]chromen-2(8*H*)-one], is a pyranocoumarin derivative formed by the bromination of seselin, which is a naturally occurring angular pyranocoumarin isolated from the Indian herb *Trachyspermum stictocarpum*. In the molecule, the benzopyran ring system is essentially planar, with a maximum deviation of 0.044 (2) Å for the O atom. The dihydropyran ring is in a half-chair conformation and the four essentially planar atoms of this ring form a dihedral angle of 4.6 (2)° with the benzopyran ring system. In the crystal, molecules are linked by weak C—H···O hydrogen bonds, forming chains propagating along [010]. In addition, π - π stacking interactions, with centroid–centroid distances of 3.902 (2) and 3.908 (2) Å, link the hydrogen-bonded chains into layers parallel to (001).

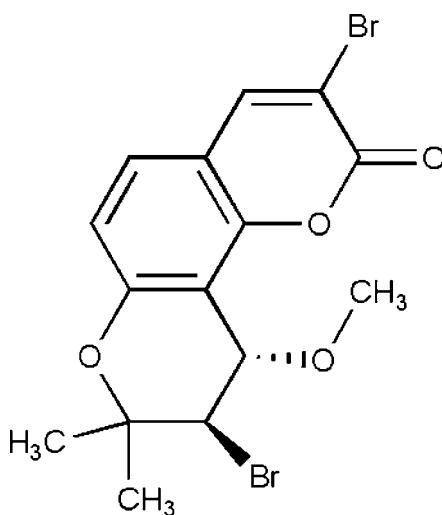

1. Chemical context

The title compound is a substituted product of seselin containing two bromine atoms and a methoxy group. This class of pyranocoumarins have an absorption band in the near-UV region due to the presence of extended conjugated double bonds and exhibit photomutagenic (Appendino *et al.*, 2004) and photocarcinogenic properties to bind with the purin base of DNA in a living cell to yield photoadducts (Conforti *et al.*, 2009). Based on the properties of these molecules, they are employed for the treatment of numerous inflammatory skin diseases such as atopic dermatitis and the pigment disorders vitiligo and psoriasis on exposure to ultra violet (UV) radiation in photodynamic therapy (PDT). It has also been found that as a result of their strong ability for absorption of UV radiation, they are utilized as photoprotective agents to prevent the absorption of harmful UV radiation by the skin in the form of a variety of sun-screening lotions widely used in dermatological applications in the cosmetic and pharmaceutical industries (Chen *et al.*, 2007, 2009). In addition to these activities, antiproliferative activity and photo-toxicity of related coumarin molecules has been reported against numerous cancer cell lines such as HL60, A431 (Conconi *et al.*, 1998). Inhibited proliferation in the human hepatocellular carcinoma cell line has also been reported (March *et al.*, 1993). Recently, this type of molecule has been connected as a spacer with porphyrin moieties to obtain a scaffold-type macromolecule (molecular nanotweezers) and has been employed to study the interaction (host–guest interaction) with fullerenes

OPEN ACCESS

such as C₆₀ and C₇₀ (Banerjee *et al.*, 2014; Ghosh *et al.*, 2014) in supramolecular chemistry and material science. Molecular tweezers containing a coumarin moiety showed better quantum yield and fluorescence absorption as a result of the presence of the extended conjugated enone of pyranocoumarin. As part of our ongoing studies in this area, we herein describe the synthesis and structure of the title molecule.

2. Structural commentary

The title molecule (Fig. 1) is composed of three different types of rings *viz.* benzene, pyran and dihydropyran. The benzopyran ring system C1/C5–C12/O2 is essentially planar with a maximum deviation of 0.044 (2) Å for atom O2. The dihydropyran ring C1–C5/O1 is in a half-chair conformation and atoms C2 and C3 deviate by –0.385 (4) and 0.280 (4) Å from the plane through the other four essentially planar atoms (mean deviation 0.003 Å), which makes a dihedral angle of 4.6 (2)° with the benzopyran ring system. The relative stereochemistry at atoms C3 and C4 is *R/S* and *S/R*.

D–H···A	D–H	H···A	D···A	D–H···A
C11–H11···O4 ⁱ	0.93	2.57	3.188 (6)	124

Symmetry code: (i) $x, y - 1, z$.

3. Supramolecular features

In the crystal, molecules are linked by weak C–H···O hydrogen bonds (Table 1), forming chains propagating along [010] (Fig. 2). In addition, π – π stacking interactions with centroid–centroid distances $Cg1 \cdots Cg1(2 - x, -y, 1 - z)$ of 3.902 (2) Å and $Cg1 \cdots Cg2(1 - x, -y, 1 - z)$ of 3.908 (2) Å where $Cg1$ and $Cg2$ are the centroids of the C1/C5/C6/C10–C12 and O2/C6–C10 rings, respectively, link the hydrogen-bonded chains, forming layers parallel (001) (Fig. 3).

4. Database survey

A search of the Cambridge Structural Database (CSD, Version 5.38, update November, 2016; Groom *et al.*, 2016) gave more than thirty five hits for both linear and angular pyranocoumarin (psoralen class) structures. They include closely related structures [CSD refcodes AMYROL (Kato, 1970), FUGVOS (Thailambal & Pattabhi, 1987), AMYROL01 (Bauri *et al.*, 2006, 2017)] and a number of structures with various substituents at C3 and C4, many of which are natural products.

5. Synthesis and crystallization

The title compound is a colourless solid substance formed on bromination of the naturally occurring seseline isolated from the methanol extract of *T. stictocarpum* by means of column chromatography over SiO₂ gel with gradient elution by using a mixture of the binary solvents hexane and ethyl acetate. The bromination was conducted using NBS in methanol at room temperature with continuous stirring by means of mechanical stirrer over a period of 12 h. The reaction product was worked up by the usual method to yield crude product, which was then purified by solvent elution to yield the title compound. A colourless prism-shaped crystal was obtained after recrystallization (×3) from ethyl acetate:hexane (1:4) at room temperature by slow evaporation of the solvents. NMR analysis: ¹H NMR data (CDCl₃, 200 MHz): δ_H 8.02 (s, 1H, H-9), 7.32 (d, 1H, J = 8.80 Hz, H-12), 6.82 (d, 1H, J = 8.80 Hz, H-11), 5.36 (d, 1H, J = 6.8 Hz, H-4), 4.26 (d, 1H, J = 6.8 Hz, H-3), 3.56 (s, 3H, -OCH₃, H-13), 1.50 (s, 3H, CH₃, H-13), 1.54 (s, 3H, CH₃, H-14).

6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 2. H atoms were included in calcu-

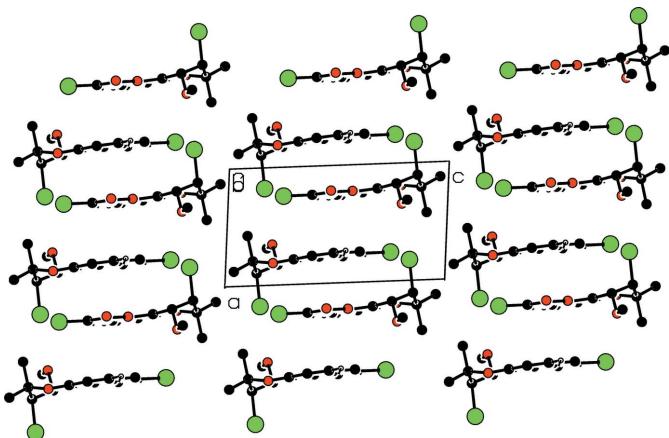

Figure 3

Data collection

Oxford Diffraction Xcalibur single-crystal X-ray diffractometer with a Sapphire CCD detector	$T_{\min} = 0.364$, $T_{\max} = 0.423$
Radiation source: fine-focus sealed tube	5172 measured reflections
Graphite monochromator	2764 independent reflections
Rotation method data acquisition using ω and phi scans.	2144 reflections with $I > 2\sigma(I)$
Absorption correction: multi-scan (CrysAlis RED; Oxford Diffraction, 2009)	$R_{\text{int}} = 0.015$
	$\theta_{\max} = 25.4^\circ$, $\theta_{\min} = 2.6^\circ$
	$h = -8 \rightarrow 8$
	$k = -8 \rightarrow 10$
	$l = -16 \rightarrow 12$

Refinement

Refinement on F^2	0 restraints
Least-squares matrix: full	Primary atom site location: structure-invariant direct methods
$R[F^2 > 2\sigma(F^2)] = 0.035$	Secondary atom site location: difference Fourier map
$wR(F^2) = 0.116$	Hydrogen site location: inferred from neighbouring sites
$S = 0.85$	
2764 reflections	
193 parameters	

H-atom parameters constrained
 $w = 1/[\sigma^2(F_o^2) + (0.1P)^2]$
 where $P = (F_o^2 + 2F_c^2)/3$

$(\Delta/\sigma)_{\max} = 0.004$
 $\Delta\rho_{\max} = 0.46 \text{ e } \text{\AA}^{-3}$
 $\Delta\rho_{\min} = -0.42 \text{ e } \text{\AA}^{-3}$

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R-factor wR and goodness of fit S are based on F^2 , conventional R-factors R are based on F, with F set to zero for negative F^2 . The threshold expression of $F^2 > 2\text{sigma}(F^2)$ is used only for calculating R-factors(gt) etc. and is not relevant to the choice of reflections for refinement. R-factors based on F^2 are statistically about twice as large as those based on F, and R-factors based on ALL data will be even larger.
