**Abstract** Avascular or aseptic necrosis is a well-defined entity leading to the degradation of cellular elements of the bone. The pathogenesis of osteonecrosis (ON) is still unknown. There are two main types of ON: traumatic or non-traumatic. Several clinical entities could associate with ON, systemic diseases, environmental factors, pregnancy, systemic autoimmune or rheumatic diseases, thrombophilia, corticosteroid therapy, cytotoxic drugs, infections, metabolic and hematologic diseases, etc. Corticosteroids (CS) are still the most frequently used therapeutic options in the early phase and during flares of these diseases. Inflammatory cytokines and antibodies have been described to participate in the pathogenesis of ON. The infiltrative disorders of the bone marrow could also contribute to the development of ON. Hereby, we describe a female patient with NHL followed by SLE in whom ON has developed at least in two localisations. Lupus flare, long-term CS therapy, lymphoma relapse or the presence of antiphospholipid antibodies were excluded. Although the bi-localised ON could be contributed to immunologic factors or trauma, the exact aetiology in this case could not be elucidated.

**Keywords** Antiphospholipid antibodies · Aseptic necrosis · Corticosteroid · NHL · SLE

Avascular or aseptic necrosis is a well-defined entity leading to the degradation of cellular elements of the bone. The pathogenesis of osteonecrosis (ON) is still unknown. There are two main types of ON: traumatic or non-traumatic. Several clinical entities could associate with ON, systemic diseases, environmental factors, pregnancy, systemic autoimmune or rheumatic diseases, thrombophilia, corticosteroid therapy, cytotoxic drugs, infections, metabolic and hematologic diseases, etc. There are some systemic autoimmune diseases, such as systemic lupus erythaematosus (SLE), antiphospholipid syndrome (APS) and vasculitis which may associate more frequently with ON than others (1). Corticosteroids (CS) are still the most frequently used therapeutic options in the early phase and during flares of these diseases (2). Inflammatory cytokines and antibodies have been described to participate in the pathogenesis of ON. The infiltrative disorders of the bone marrow could also contribute to the development of ON; however, in non-Hodgkin's lymphomas (NHL), no clear association with ON have been shown previously (1). Hereby, we describe a female patient with NHL followed by SLE in whom ON has developed at least in two localisations. Lupus flare, long-term CS therapy, lymphoma relapse or the presence of antiphospholipid antibodies were excluded. Although the bi-localised ON could be contributed to immunologic factors or trauma, the exact aetiology in this case could not be elucidated.

We report a case of a 32-year-old Caucasian woman with large B cell mediastinal NHL treated with radiotherapy and autologous bone marrow transplantation. Following the therapy, she got in remission. Later, at the age of 40, she complained for fever and polyarthritis. The relapse of the NHL was suspected therefore positron emission tomography

(PET) was performed with normal result. Besides polyarthritis, ANA, a-dsDNA, leukopenia and anaemia developed; SLE was diagnosed. She was treated with short-term high-dose CS, followed by low-dose CS, only for a 1-year period (preventing flares), and chloroquine as maintenance therapy was administered. Brain magnetic resonance imaging (MRI), which was performed due to migraine, detected few small, micro-lacunar, ischemic, micro-vascular lesions, which could be considered as vasculitis. In January 2012, she complained for severe right hip pain. Aseptic necrosis of the femur head was verified with MRI. Because of the movement restriction and persistent pain, a total endoprosthesis was implanted into the right hip. Histopathology was consistent with aseptic osteonecrosis without any signs of malignancy either in the bone cortex or bone marrow spaces. The surgical intervention was completed with a complex rehabilitation. In June 2011, severe left shoulder pain developed. The MRI showed several subchondral lythic and sclerotic spaces with particular fractures in the head of the humerus, characteristic findings for aseptic bone necrosis. Both native CT, FDG-PET and laboratory investigations excluded malignancy, infection or the reoccurrence of NHL. There were no clinical or laboratory signs indicating relapse of SLE. None of the antiphospholipid antibodies were detected since disease onset. Quantiferon tests for tuberculosis were negative. The serum bone turnover biochemical markers and parathormone, TSH, and also 25-OH vitamin D level were normal. Dual X-ray absorptiometry showed mild osteopenia. The patient did not drink alcohol habitually; there was no evidence for hyperlipidaemia or coagulopathy.

Since the patient received high-dose CS only in the early phase of the disease (SLE) for remission inductions and CS was gradually tapered then omitted, the treatment could not be the cause for the aseptic ON. Presently, she is a recipient for prosthesis of the left shoulder and also for arthroscopy or synovectomy of the left elbow.

ON is a clinical feature leading to the degradation of bone marrow and trabecular bone, resulting in the collapse of bone architecture. Clinically, it is manifested in bone and joint pain, bone destruction and loss of function, although it could remain silent for a long time. However, the pain also can develop rapidly and can be very intensive, especially when caused by large infarcts of the femoral head. The aseptic, or as a synonym, avascular necrosis may be caused by several factors, including local trauma or non-traumatic systemic diseases. The predisposing factors are alcoholism; iatrogenic agents; pancreatitis; hematologic, metabolic or endocrine disorders; pregnancy; neoplastic diseases; systemic autoimmune; rheumatic diseases; or orthopaedic disorders. Approximately, in 75 % of the cases, ON starts between the ages of 30 and 60 years. The frequency of avascular necrosis in SLE ranges from 3 to 30 %; however, a higher frequency (40 %) was reported in children and young patients with lupus (1).

CS are reported as major risk factors for development of ON in SLE, where steroids are usually the most frequently applied treatment options in the early phase or flares of the disease. ON occurs mainly in SLE patients who are treated with CS and is extremely rare among those who have never received CS (2, 3). However, another retrospective study has shown no relationship between the risk of ON development and the total dose, duration of steroid therapy and disease activity (4). However, vasospasm, cushingoid feature, vasculitis, smoking, pre-eclampsia and the presence of lupus anticoagulant are suspected to be associated with increased risk of ON (4).

SLE is often associated with APS (5). In our case, the patient had no presence of antiphospholipid antibodies [anticardiolipin antibody (aCL), lupus anticoagulant and anti- $\beta$ 2-glycoprotein-I]. There are some case reports and studies describing the strong association between primary and secondary APS and ON (6, 7). However, no difference in the prevalence of aCL in patients with or without ON were found previously (8, 9). A clearly increased risk for NHL has been described in patients with SLE as compared to those in the general population. It has still remained unclear to what extent the association with NHL is mediated by innate versus exogenous factors (10, 11). Interestingly, diffuse, large B cell lymphoma was the first disease in our case preceding lupus. Therefore, paraneoplastic syndrome had to be accounted, although lymphoma was confirmed being in remission when SLE developed. Primary or metastatic bone cancer was excluded in our case and bone turnover biomarkers were normal. In myeloma multiplex (MM), osteoclast activation and osteoblast inhibition have been described (12). Myeloma cells lead to an imbalance in the receptor activator of nuclear factor-kappa B/receptor activator of nuclear factor-kappa B ligand (RANK/RANK-L)-system in the tumour microenvironment, such as the receptor activator of nuclear factor-kappa B ligand/osteoprotegerin (RANK-L/OPG) ratio is essential for normal bone turnover. Myeloma cells induce RANK-L expression and decrease OPG secretion by osteoblasts and stromal cells (13, 14). There are other pathways of MM in the development of ON, as myeloma cells produce and shed syndecan (CD 138) that binds to the heparin-binding domain of OPG and mediates its internalisation and lysosomal degradation by myeloma cells. Other cytokines, as MIP-1 $\alpha$  and MIP-1 $\beta$  enhance RANK-L expression in stromal cells. MIP-1 $\alpha$  promotes growth, survival and migration of myeloma cells (15). There are two basic and common cytokines, interleukin (IL)-6 and IL-11, which are predominantly produced by stromal cells, as well as inflammatory cells involved in SLE (16). Both the upregulation of IL-6 secretion through cell-to-cell contact and the downregulation of OPG result in increased osteoclast activation and a consequent bone resorption. Less defined in lupus, but the IL-3, hepatocyte growth factor (HGF), SDF-1 $\alpha$  and its receptor CXCR4 are expressed on

osteoclast precursors, which all increase osteoclast motility and bone-resorpting activity. Other similar ON-provoking factors, as MMP-1 and MMP-2, urokinase plasminogen activator and HGF, are recognised both in MM and lupus (17, 18). Presumably, these factors may lead to avascular necrosis of the bone in NHL. Bernbeck et al. described bone marrow oedema and aseptic necrosis in children and adolescent with acute lymphoblastic leukaemia or NHL treated with hyperbaric oxygen therapy, whereas the ON was contributed to the treatment rather than the haematologic disease (19). In MM, there are some promising therapeutic options, as antibodies to MIP-1 $\alpha$  and MIP-1 $\beta$  or DKK-1 gene produced protein which could be also effective in lupus-associated ON (20). Anti-IL-6 and anti-IL-3 may be common therapeutic options in lupus and associated ON (16, 21), while shared therapeutic targets between lupus and myeloma, such as proteasome inhibitors also can be considered in these patients (22, 23). We believe that the development of ON in our patient was due to a systemic immune activation, pro-inflammatory cytokine secretion and presumably altered RANK/RANKL system. Targeting pro-inflammatory cytokines and anti-resorptive therapy can be beneficial in lupus patients with ON.
