18 **Abstract**

19 Most sudden cardiac deaths in young people arise from hypertrophic cardiomyopathy,
20 a genetic disease of the heart muscle, with many causative mutations found in the
21 molecular motor beta-cardiac myosin that drives contraction. Therapeutic intervention
22 has until recently been limited to symptomatic relief or invasive procedures. However,
23 small molecule modulators of cardiac myosin are promising therapeutic options to
24 target disease progression. Mavacamten is the first example to gain FDA approval but
25 its molecular mode of action remains unclear, limiting our understanding of its
26 functional effects in disease. To better understand this, we solved the cryoEM
27 structures of beta-cardiac heavy meromyosin in three ADP.Pi-bound states, the primed
28 motor domain in the presence and absence of mavacamten, and the sequestered
29 autoinhibited interacting-heads motif (IHM) in complex with mavacamten, to 2.9 Å, 3.4
30 Å and 3.7 Å global resolution respectively. Together with quantitative crosslinking mass
31 spectrometric analysis, these structures reveal how mavacamten inhibits myosin.
32 Mavacamten stabilises ADP.Pi binding, stalling the motor domain in a primed state,
33 reducing motor dynamics required for actin-binding cleft closure, and slowing
34 progression through the force generation cycle. Within the two-headed myosin
35 molecule, these effects are propagated and lead to stabilisation of the IHM, through
36 increased contacts at the motor-motor interface. Critically, while mavacamten

37 treatment can thus rescue cardiac muscle relaxation in diastole, it can also reduce

38 contractile output in systole in the heart.

39

40 **Introduction**

41 Hypertrophic cardiomyopathy (HCM) affects at least 1 in 500 people and is the most

42 common cause of heart failure in the young[1]. It is a genetic disease of the sarcomere,

43 with ~40 % of known disease-causing mutations found in the beta-cardiac myosin

44 (βCM) heavy chain gene (MYH7) [2] and causing ~30% of disease cases[3]. The exact

45 disease mechanism(s) for HCM remains unclear. Treatment typically involves

46 symptomatic relief, with beta or calcium channel blockers, or invasive procedures,

47 such as septal myectomy, which do not address the root cause of disease[4]. More

48 recently, small molecule treatments have been developed to directly modulate βCM

49 force production[5] and tackle disease progression. Mavacamten[6,7] is the first of these

50 to be FDA approved, with many others in clinical trials[8,9]. However, our understanding

51 of the molecular mechanism of mavacamten is limited, restricting our understanding

52 of its functional effects within disease.

53 βCM is the molecular motor responsible for force generation in cardiac ventricular

54 tissue[10], fuelled by ATP and through its interaction with filamentous actin. A single βCM

55 molecule is comprised of two heavy chains and four light chains, of which two are

56 essential (ELC) and two regulatory (RLC). Each heavy chain consists of an N-terminal

57 globular motor domain, light chain binding domain (LCD) (where one ELC and one

58 RLC bind) followed by an alpha helical region through which two heavy chains

59 dimerise to form a coiled coil. The coiled coil is further divided into subfragment 2 (S2)

60 and the filament-forming light meromyosin (LMM). Each motor domain is divided into

61 four subdomains, the N-terminal domain, lower 50k domain (L50), upper 50k domain

62 (U50) and the converter that together with the LCD forms the lever[11,12].

63 Myosin molecules form bipolar filaments, with their LMM tails in the filament backbone

64 and their paired motor domains on the filament surface[13,14]. To drive contraction they

65 work in concert, interacting with actin to generate force transmitted by their levers in

66 response to nucleotide and actin-binding state[12]. The motor domain together with the

67 lever, collectively termed S1 or a myosin head, as well as cardiac heavy meromyosin

68 (cHMM) (myosin lacking its LMM region), are competent to produce force and thus

69 frequently studied to understand the myosin mechanochemical cycle.

70   Upon ATP binding a myosin head undergoes lever priming and ATP hydrolysis, to form

71   a primed conformation[15,16]. In this ADP.Pi bound state myosin has an open actin-

72   binding cleft between the U50 and L50 domains and can only interact with actin

73   weakly. Conformational change within the motor leads to stronger actin-binding, cleft

74   closure, Pi release and myosin lever swing (powerstroke), generating force[17,18]. ADP

75   release from the motor results in a further, more minor, shift in lever position[19]. Re-

76   binding of ATP opens the actin binding-cleft, disassociating the motor from actin and

77   the cycle starts again[15]. Phosphate release is the rate limiting step for βCM in both the

78   absence (basal turnover) and presence of actin[20,21].

79   Within the heart, muscle contraction and thus force production are tightly regulated by

80   two distinct mechanisms[22]. Actin thin filament regulation acts as an on-off switch,

81   controlling when contraction can occur through intracellular calcium levels dictating

82   when sites on actin are available for myosin binding[23]. Myosin thick filament regulation

83   fine tunes the force output of individual thick filaments by controlling the number of

84   motors available to produce force within the filament[24]. To do this, βCM can form a

85   sequestered state outside of the force generation cycle called the interacting-heads

86   motif (IHM).

87   The IHM forms through the asymmetric interaction of two ADP.Pi bound primed motors

88   from the same molecule folding down against their S2 coiled coil[13,14]. Within the IHM

89   one of the heads (termed the blocked head: BH) is blocked from interacting with actin

90   as its actin-binding cleft is sequestered by the converter of the other head (termed free

91   head: FH). In filaments, the IHM state is further stabilised through interactions with the

92   thick filament backbone, titin and myosin-binding protein C[13,14].

93   In HCM, the number of βCM molecules available to interact with actin and produce

94   force are hypothesised to increase[25,26], resulting in diminished relaxation and the

95   diastolic dysfunction observed clinically[27]. Thus, HCM may potentially be treated by

96   therapeutics which either inhibit myosin activity or increase IHM formation.

97   Mavacamten is a cardiac myosin allosteric inhibitor that inhibits sarcomeric force

98   production, reducing cardiac contraction in animal models, isolated cells and muscle

99   fibres[28]. It inhibits basal and actin-activated ATPase activity by inhibiting Pi release

100   and stabilises an autoinhibited off-state[29], reducing the number of functionally

101   available motors to generate contractile force[28]. However, although mavacamten can

102   stabilise an autoinhibited off-state[29], the detailed structural nature of this state, the

103   mechanism of this stabilisation, and how it inhibits Pi release are unclear[30].

104   Several recent studies have begun to build on biochemical observations and unpick
105   the structural mechanism of mavacamten. Three cryoEM structures have resolved the
106   human cardiac thick filament, two in the presence[13,14] and one in the absence of
107   mavacamten[31]. These structures demonstrated that mavacamten stabilises the IHM
108   but do not have sufficient resolution (resolutions ranging from ~20 Å to 6 Å) to observe
109   the underlying mechanism. Additionally, a recent crystal structure of a bovine S1
110   fragment complexed with ADP.BeFx and mavacamten showed the mavacamten
111   binding site and that it restrains the lever[32]. The authors used molecular dynamic
112   simulations to investigate how mavacamten inhibits myosin activity and proposed that
113   mavacamten binding alters the L50 domain actin-binding interface to form a motor
114   incompetent for force generation[32]. Yet this proposed mechanism does not explain
115   how mavacamten inhibits Pi release.
116   Here, we performed a comprehensive analysis of the effects of mavacamten on
117   cardiac myosin, from in vitro motility assays to structure determination by cryoEM and
118   cross-linking studies using mass spectrometry. We show how mavacamten
119   allosterically stabilises the IHM and inhibits Pi release from individual motor domains.
120   We see no evidence for a significantly altered L50 domain structure or destabilisation
121   of the L50 domain helix-loop-helix actin-binding interface upon mavacamten binding,
122   as recently proposed[32]. In the context of the thick filament structures[13,14,31], as well as
123   recent observations made on the actin activation of myosin[18], our data allow us to
124   present a full structural mechanism for mavacamten inhibition of myosin.

125

126   **Results**

127

128   **Mavacamten stabilises an off-pathway stalled ADP.Pi state**
129   To ensure our cHMM construct was functionally active and inhibited by mavacamten,
130   as expected, we tested its ability to drive actin filament movement by use of an in vitro
131   filament gliding assay[33] in comparison to a single-headed myosin construct (cS1)
132   (Extended Data Fig. 2, Supplementary Table. 1). The mavacamten concentration
133   required to reduce motility to 50% (IC$_{50}$) was 0.14 μM for cHMM and ~4-fold higher for
134   cS1 (0.62 μM) (consistent with previous reports[28]). When filament movement was
135   tracked over time in the presence of mavacamten, we observed that the number of
136   moving filaments did not change for cS1 but decreased for cHMM in a dose dependant
137   manner (Extended Data Fig. 2d, Supplementary Movie 1), consistent with the cHMM

138   construct forming the IHM and reducing the number of motors available to interact with

139   actin and produce movement.

140   To corroborate this, we examined the ratio of open head to IHM cHMM molecules in

141   the presence and absence of mavacamten (Extended Data Fig. 3) using a negative

142   stain EM assay. We found that mavacamten significantly (P=0.0002, determined by

143   an unpaired two-tailed student's T-test with respect to the βCM control) increased the

144   percentage of cHMM molecules in the IHM when compared to cHMM alone.

145   To understand how mavacamten elicits these effects we used cryoEM to solve the

146   structure of the cHMM motor domain in an open heads conformation, in the presence

147   (MD$_{mava}$) and absence of mavacamten (MD), and the cHMM IHM conformation in the

148   presence of mavacamten (IHM$_{mava}$) (see Methods, Extended Data Fig. 1 &

149   Supplementary Fig. 1 & 2 respectively).

150   We pre-incubated cHMM with ATP to enable formation of open and IHM ADP.Pi states

151   prior to the addition of mavacamten (or DMSO as control), followed by subsequent

152   cross-linking with BS3 (see Methods). We then optimised cryoEM grid and vitrification

153   conditions for imaging either cHMM molecules in the open state or in the IHM, which

154   were then selected for downstream processing accordingly (see methods).

155   The MD$_{mava}$ and MD were resolved to 2.9 Å and 3.4 Å global resolution respectively

156   (Supplementary Fig. 1; Supplementary Table. 2). To interpret the cryoEM density maps

157   we built pseudo-atomic models using a homology model and molecular dynamics

158   driven flexible fitting[34] (Supplementary Table. 3). Both maps showed density for

159   MgADP.Pi and a primed lever with associated ELC density, confirming they were in a

160   primed conformation (Extended Data Fig. 4, Fig. 1.)

161   Mavacamten was clearly resolved, positioned between the converter and the U50 (Fig.

162   1a). The mavacamten-protein interactions are predominantly hydrophobic formed by

163   the sidechain backbones of residues R721, L770, and I713 on the converter with

164   isopropyl pyrimidinedione, methylethyl ester and phenyl moieties of mavacamten (Fig.

165   1b-c) as well as H666 on the L50 and T167 on the U50 with the isopropyl

166   pyrimidinedione and phenyl moieties. These hydrophobic contacts are then further

167   supported by an ionic interaction between Y164 on the U50 and the isopropyl

168   pyrimidinedione moiety and hydrogen bonding between N711, the backbone of R712

169   from the converter, and D168 from the U50 to the isopropyl pyrimidinedione and

170   methylethyl ester moieties (Fig. 1b-c).

171 Binding of mavacamten rotates the lever 9° towards the U50 of the motor,

172 perpendicular to the working stroke, when compared to the canonical primed MD

173 conformation (Fig. 1d). This allows formation of a salt bridge between D778 and K146,

174 creating additional communication between the lever and U50 domain (Fig. 1;

175 Supplementary Movie. 2). Thus, mavacamten acts as a molecular glue, bonding the

176 lever against the U50.
178 **Figure 1. Mavacamten restrains the lever and D helix.** (a) Segmented cryoEM map of the

183 hydrophobic R721, L770, I713, H666 and T267 ; Ionic: Y164 and hydrogen bonding from
184 N711, R712 and D168 (d) Overlay of MD grey and MD$_{mava}$ coloured and segmented maps
185 (contour MD: 0.5, MD$_{mava}$: 0.6) showing 9° shift in the lever due to Mavacamten binding (global
186 alignment).

188 To understand how mavacamten may affect the association of myosin with actin in the

189 weakly-bound ADP.Pi state, we aligned the MD and MD$_{mava}$ structures on the L50 helix-

190 loop-helix (HLH), the primary actomyosin binding interface[18]. Mavacamten binding

191   subtly shifts the U50 relative to the L50, pinching the actin binding cleft in a motion
192   distinct from cleft closure (Fig. 2a,b; Supplementary Movie. 2). This may be driven by
193   the increased communication between the lever and the U50, which moves the D-
194   helix towards the active site, altering the relative position of Y134 and nucleotide (Fig.
195   2c-e), compressing the ADP.Pi binding site.

196   The shift of the U50 domain towards the L50 domain results in several rotamer
197   changes around the backdoor, an ionic interaction between E466 and R243 that blocks
198   the phosphate exit tunnel in the primed conformation[18]. I478 adopts a rotamer
199   conformation facing the backdoor and the E466 side chain is rotated such that the
200   distance between the R243 nitrogen (NH1) and E466 oxygen (OE1) is reduced from
201   3.2Å to 2.7Å (Fig. 2f-h; Supplementary Movie. 2). This shows that in the presence of
202   mavacamten the back door interaction is stabilised, which may reduce the likelihood
203   of Pi release.

204   These structural observations are not seen in the crystal structure of bovine S1 in
205   complex with mavacamten (PDB ID: 8QYQ)[32] Extended Data Fig. 5). Thus, our
206   cryoEM structures demonstrate how mavacamten stabilises a stalled ADP.Pi state,
207   and provide structural evidence for the mechanism of inhibited Pi release[29,32,35].

208   It is important to note that the mavacamten induced structural changes are
209   directionally opposed to those observed upon actin activation[18], where the release of
210   the Pi is accelerated ~100-fold. Recent structural observations for myosin-5 have
211   shown that upon initial binding of myosin to actin the U50 domain, particularly the D-
212   helix, is cocked back towards the converter. This cocking back motion expands the
213   nucleotide pocket destabilising the free Pi and promotes cleft closure[18]. Thus, we
214   wondered whether mavacamten binding through cocking of the U50 forward,
215   stabilising ADP.Pi binding, may also reduce motor domain dynamics to limit cleft
216   closure. This would slow the transition from weak to strong binding of myosin to actin
217   in the mechanochemical cycle, which is needed to sustain force and enable Pi release.

218
Figure 2. Mavacamten binding shifts the D-helix position stabilising Pi in the active site. Mavacamten binding reduces myosin lever and actin-binding cleft dynamics

To investigate the effect of mavacamten on primed motor lever and actin-binding cleft dynamics, we used a quantitative crosslinking mass spectrometry (qXL-MS) approach. We used the MS-cleavable, amine and hydroxyl reactive cross-linker, disuccinimidyl dibutyric urea (DSBU) to crosslink cS1 ADP.Pi in the absence and presence of mavacamten and then identified and quantified the crosslinks obtained using a label-free qXL-MS comparative approach[36-38]. 85 unique interpeptide cross-links and 49 monolinks changed in normalised signal intensity by at least two-fold between the two conditions (see Supplementary Material 1 & 2), indicating that adding mavacamten significantly affected cS1 conformational dynamics.

To interpret the effects of mavacamten on cS1 dynamics, we generated S1 models, $S1_{mava}$ and S1 in the presence and absence of mavacamten, by superimposing the FH lever, ELC and RLC from our IHM_{mava} model (see Fig. 4a) onto our MD_{mava} and MD structures respectively. We then annotated the models with crosslinks that significantly increased or decreased in signal intensity 2-fold accordingly and measured their $C\alpha$-$C\alpha$ distances (Supplementary Table 4, $p<0.05$ across three replicates). Crosslinks within the accepted DSBU reaction distance of 30 Å $C\alpha$-$C\alpha$ were expected[39]. Comparatively, the observation of a crosslink between two residues with a $C\alpha$-$C\alpha$ distance >30 Å indicated conformational dynamics that allowed the two reacting side chains to come into range.

Thus, if an increase in a crosslink signal intensity in the presence of mavacamten was observed with the same $C\alpha$-$C\alpha$ distance in both $S1_{mava}$ and S1 models, the rise in signal intensity indicated increased sampling of that conformational state and reduced dynamics. Whereas, an increase in signal intensity for a crosslink with a $C\alpha$-$C\alpha$ distance >30 Å would suggest increased dynamics, as there was an increase in reactivity, e.g. increased time in which the two residues sampled a conformation outside our model in sufficient proximity to react.

To enable understanding of the changes in conformational dynamics that occur between individual motor subdomain domains, or the motor and LCs, on the addition of mavacamten, we focussed on interpreting interdomain crosslinks. 45 of the identified crosslinks were interdomain, of which we could annotate 29 on our models (Fig. 3a,b; Supplementary Table 4). The remainder could not be annotated as they

261 were located within unmodelled or flexible regions, such as the N-terminal extension

262 of the ELC or myosin loop2.

263 In the presence of mavacamten, the number of crosslinks (<30 Å $C\alpha$-$C\alpha$ distance)

264 increased significantly between residues that connect the U50 domain to the ELC (Fig.

265 3a,c; Supplementary Table 4). This is consistent with the lever being pulled in towards

266 the U50 domain when mavacamten binds, as observed in our cryoEM structures (Fig.

267 1). Crosslinking was also increased between the RLC (K115 and K111), and the LCD

268 (K803), and loop1 (S205). The RLC-loop1 crosslinks had a $C\alpha$-$C\alpha$ distance >30 Å in

269 our S1 models but would have a $C\alpha$-$C\alpha$ distance <30 Å if the lever was bent at the

270 pliant point, forming the IHM blocked head lever position (Fig. 3d). Thus, these

271 crosslinks can also be interpreted to indicate increased proximity of lever position

272 relative to the U50 domain in the presence of mavacamten (Supplementary Table 4).
273 In the presence of mavacamten, the number of crosslinks between the base of the

274 converter (CON) and the L50 domain (K707$_{L50}$-K757$_{CON}$, K707$_{L50}$- T761$_{CON}$) (Fig. 3e)

275 increased significantly, without an increase in $C\alpha$-$C\alpha$ distances in our S1 models,

276 indicating increased stability of L50-converter position. Exploratory crosslinks ($C\alpha$-$C\alpha$

277 distance >30 Å) between the ELC T72 and K98 and N-terminal domain (K21, K34 and

278 K50) and converter (K707) respectively were significantly decreased in the presence

279 of mavacamten (Fig. 3b,e). This suggests that the lever position is less dynamic,

280 exploring a narrower range of primed conformations, preventing sampling of states

281 that would allow these crosslinks to form.

282 When considering actin-binding cleft dynamics, the cleft is ordinarily thought to open

283 and close rapidly on the µs timescale[16] but with an equilibrium strongly favouring the

284 open cleft position, and thus retention of Pi in the active site. In the presence of

285 mavacamten, crosslinks (<30 Å $C\alpha$-$C\alpha$ distance) between the HCM loop in the U50

286 domain (K405 and K413), and the strut (K598) and C-terminal end of loop2 (T646)

287 within the L50 domain (Fig. 3f; Supplementary Table. 4), bridging the actin-binding cleft

288 increase in signal intensity. This suggests that cleft dynamics are reduced when

289 mavacamten binds, as there is an increase in sampling of conformations which enable

290 these crosslinks to form. This reduction in cleft dynamics may help prevent the weak

291 to strong binding transition, inhibiting phosphate release and effective actomyosin

292 cross-bridging.

293 Crosslinking of loop2 (K633-K640) to loop2 K633 and L50 K657, also significantly
294 increased, alongside a decrease in K657-K450 crosslinking in the presence of
295 mavacamten. This suggested that the binding of mavacamten stabilises the
296 conformation of loop2 enabling K657 to more readily crosslink with K633 than with
297 K450. The number of exploratory crosslinks (>30 Å Cα-Cα distance) between U50
298 K450 and L50 K707 and T646 was reduced in the presence of mavacamten, indicating
299 reduced motor domain dynamics due to interaction with the drug.

300 Strikingly, the single crosslink between K570-K572 within loop3 of the L50 had the
301 largest increase in signal intensity in the presence of mavacamten (Supplementary
302 Material 1). This is beautifully explained when we examine the hydrogen bonding
303 network of loop 3 within the MD and MD$_{mava}$ structures respectively (Extended Data
304 Fig. 6). K570 is solvent exposed within both structures but in the presence of
305 mavacamten, an ionic interaction between D469 and K572 is lost and instead D587
306 interacts with R567. This leaves K572 without a binding partner, making it available for
307 crosslinking to K570 and accounting for this dramatic change in reactivity.

308 Although the rearrangement of this hydrogen bonding network may increase the
309 dynamics of loop 3 in the presence of mavacamten, there is a corresponding decrease
310 to the exploratory crosslink K565$_{L50}$-K707$_{L50}$, between the N-terminal end of loop3 and
311 the base of the converter (Supplementary Material 1). This allows us to reasonably
312 conclude that the localised increase in dynamics of loop 3 is due to allosteric
313 communication and not a wholesale increase of dynamics within the L50.
314 Corroborating this, we see no evidence within the cryoEM density maps for a decrease
315 in stability of the HLH in the presence of mavacamten (Supplementary information Fig.
316 1l,m).

317

Figure 3. qXL-MS analysis of crosslinks in the presence of mavacamten. Overview of crosslinks observed to (a) increase and (b) decrease in the presence of mavacamten mapped onto the S1$_{mava}$ model coloured by subdomain: N-terminal domain beige, L50 green, U50 pink, converter domain light blue, LCD dark blue, ELC light purple, RLC yellow and mavacamten burgundy. Solid lines denominate DSBU crosslinks with a <30 Å Cα-Cα distance whilst dashed lines represent crosslinks with a >30 Å Cα-Cα distance, red = increasing, purple = decreasing. (c-d) Magnified view of increasing crosslinks between the LCs and U50 subdomain, with a (c) open head and (d) BH lever position. (e) Overview of crosslinks showing increased stability of lever position in the presence of mavacamten (f) Overview of crosslinks showing changes in U50-L50 position in the presence of mavacamten. Loop2 is represented by a dotted black line. Crosslinks shown here are further described in Supplementary Table 4.

329

330   In addition to changes in crosslinking, we also observed changes to monolink signal
331   intensity, where the crosslinker reacts with a residue and solvent. Monolinks for the
332   ELC residues K142 and K147 and LCD residue K803 decrease in the presence of
333   mavacamten as the ELC and LCD residues are instead able to crosslink with the U50
334   and RLC respectively (see Supplementary Material 1). The most significant decrease
335   in monolinking in the presence of mavacamten was $K146_{U50}$, which is expected given
336   the formation of an ionic interaction between $K146_{U50}$ and $D778_{LCD}$ in the presence of
337   mavacamten in our structures that increases communication between the lever and
338   nucleotide binding site.

339   Together, our combined cryoEM and qXL-MS structural analysis suggests that
340   mavacamten stabilises ADP.Pi binding and limits actin-binding cleft closure, required
341   for the weak to strong binding transition, to inhibit phosphate release. Thus,
342   mavacamten stabilises an off-pathway stalled myosin motor conformation that is
343   unable to progress through the mechanochemical cycle.

Mavacamten restrains the IHM through stabilisation of the free head motor domain

To understand how mavacamten stabilises the IHM we used cryoEM to solve the structure of cHMM IHM in complex with mavacamten (IHM_{mava}) to a global resolution of 3.7Å (Supplementary information Fig. 2; Fig. 4a) and compared it to our MD_{mava} structure and to the mavacamten free folded-back state (IHM^{40}) previously reported (PDB ID: 8ACT)[40]. The overall appearance of the IHM_{mava} is consistent with the IHM structure. However, mavacamten binding induces distinct conformational changes within the motor domain of the BH and FH respectively.

Mavacamten is bound to both the BH and FH of the IHM_{mava} (Fig. 4b,c). The FH mavacamten binding site is compressed, with the lever domain lying even closer to the U50 than in the MD_{mava} structure (Extended Data Fig. 7) yet maintains all interactions previously observed (Fig. 4c). Conversely, due to formation of the BH lever conformation, the mavacamten BH binding site is expanded (Extended Data Fig. 7) compared to the MD_{mava} structure, and its interaction with N711 and L770 is lost (Fig. 4b). This suggests mavacamten may have a greater effect on IHM_{mava} stabilisation through its interaction with the FH.

Indeed, the structural changes caused by mavacamten in the FH are the most prominent and provide a mechanism through which allosteric IHM stabilisation occurs. Comparison of the MD_{mava} and IHM_{mava} FH, by alignment on the main body of the motor (residues 3-710), shows the IHM_{mava} FH lever adopts a much sharper angle than in the MD_{mava} structure, rotating 5° perpendicular to the lever swing (Fig. 4d). If the same comparison is performed between the IHM^{40} FH and IHM_{mava} FH a rotation of 9° is observed in the same direction (Extended Data Fig. 8). The change in FH lever angle allows the converter to form a more extensive interface with the BH, strengthening existing contacts at the $U50_{BH}$-converter$_{FH}$ interface (Fig. 4e) between $N391_{BH}$ and the backbone of $S738_{FH}$ as well as $Y386_{BH}$ and $Q734_{FH}$ (Fig. 4f).

As the FH converter now packs more tightly against the $U50_{BH}$ several new interactions form, supporting the interface. Interactions are formed between $S738_{FH}$, $S392_{BH}$ and $D382_{BH}$, $D717_{FH}$ and $K397_{BH}$ as well as $R735_{FH}$ and $N391_{BH}$ in addition to a hydrophobic interaction between $A393_{BH}$ and $L714_{FH}$ (Fig. 4f; Supplementary Movie. 3). The movement also results in rearrangement of $F735_{FH}$, which now forms a hydrophobic interface with $K383_{BH}$, $L302_{BH}$ and $Y386_{BH}$. (Fig. 4f; Supplementary Movie. 3). Interactions are also altered at the HCM loop$_{BH}$-transducer$_{FH}$ interface with

378 the formation of an ionic interaction between $D409_{BH}$ and $R249_{FH}$ (Supplementary

379 Movie. 3). Finally, a new interaction interface between the $U50_{BH}$ and the ELC_{FH} is

380 able to form between $K611_{BH}$ and $D143_{BH-ELC}$ (Supplementary Movie. 3).

381 In summary, the change in FH lever angle upon mavacamten binding provides

382 increased structural rigidity to the IHM through the generation of new interfaces,

383 strengthening the motor-motor contact, providing a structural mechanism for its

384 allosteric stabilising effects. This mechanism is supported by recent structural

385 observations in which IHM crowns in a relaxed mavacamten-free thick filament

386 structure were less ordered than in their mavacamten-bound counterparts, particularly

387 in the free head of the disordered crown/crown $2^{13,31}$.

388 The blocked head conformation within the IHM_{mava} also deviates from that observed

389 in both the MD_{mava} and the IHM^{40} structures but only in the relative positioning of the

390 U50 domain. When the MD_{mava} is aligned on the $L50_{BH}$ domain of the IHM_{mava} it is

391 apparent that the $U50_{BH}$ domain has moved across the $L50_{BH}$ towards S2. If the same

392 alignment is performed with the IHM^{40} and IHM_{mava} the same shift is observed

393 (Extended Data Fig. 9). This conformational change in the $U50_{BH}$ is needed to

394 accommodate the altered converter$_{FH}$ position upon mavacamten binding. Thus, the

395 conformational changes observed in the blocked head upon mavacamten binding are

396 a consequence of its IHM stabilising effect but not a contributor to IHM stabilisation.
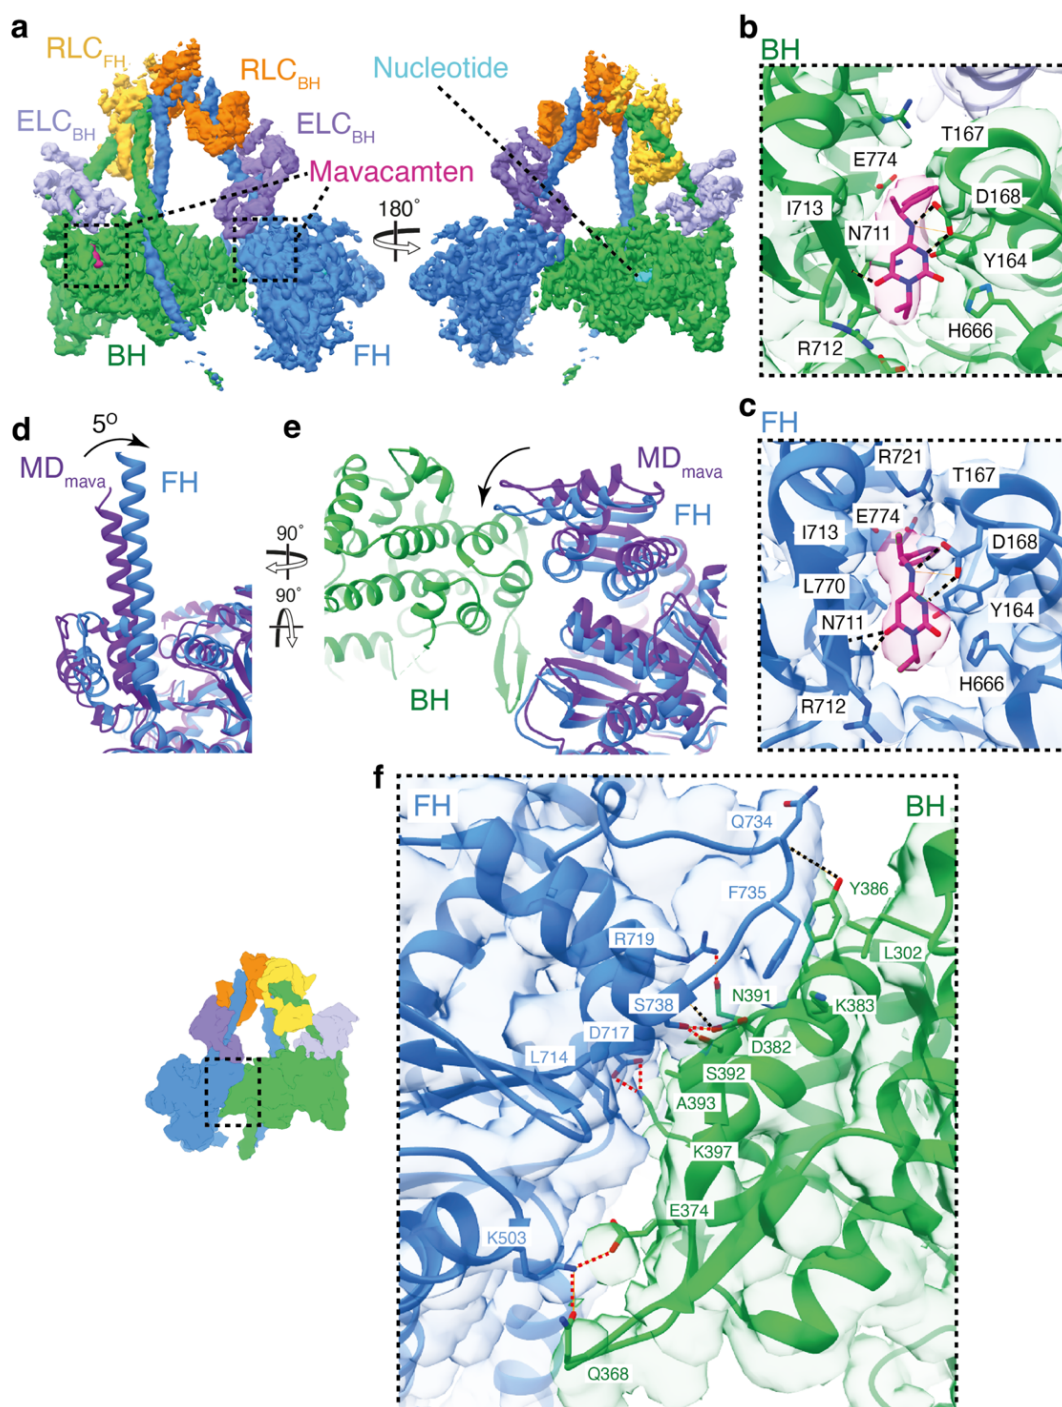

Figure 4. Mavacamten strengthens the motor-motor interface in the IHM by altering the FH lever conformation. (a) Segmented cryoEM map of the IHM_{mava} structure coloured by chain (contour: 0.08): BH green, FH blue, ELC_{BH} light purple, ELC_{FH} purple, RLC_{BH} yellow, RLC_{FH} orange, mavacamten burgundy, and the nucleotide in light blue. (b-c) The IHM_{mava} model fitted to the segmented map highlighting the BH and FH mavacamten pockets respectively. (d) Side view of the FH lever blue overlaid MD_{mava} dark purple (aligned on the motor D3-P710) highlighting the 5° shift of the lever. (e) Top-down view of (d) including the BH in green showing the movement of the free head converter. (f) Interaction interfaces between the $U50_{BH}$-converter$_{FH}$ (contour: 0.01), with H-bonds unique to the IHM_{mava} in red (compared to PDB ID: 8ACT[40]).

408   Along with stabilising the motor-motor interface, mavacamten reduces the activity of

409   the FH by restraining the nucleotide pocket. Comparison of the IHM_{mava} FH to our

410   MD_{mava} structure and IHM[40] shows the D helix$_{FH}$, is moved further towards the

411   nucleotide pocket in the IHM_{mava} structure (Fig. 5c-e; Extended Data Fig. 8). The U50$_{FH}$

412   has also shifted relative to the L50$_{FH}$ further pinching the actin binding cleft (Fig. 5a-b;

413   Extended data Fig. 8). The resulting shift of the D-helix$_{FH}$ and surrounding loops further

414   reduces the available space for ADP dynamics, increasing the stability of ADP.Pi within

415   the active site (Fig. 5f-g, Extended data Fig. 8e). Once again this is an opposite motion

416   to that observed during actin activation[18].

417
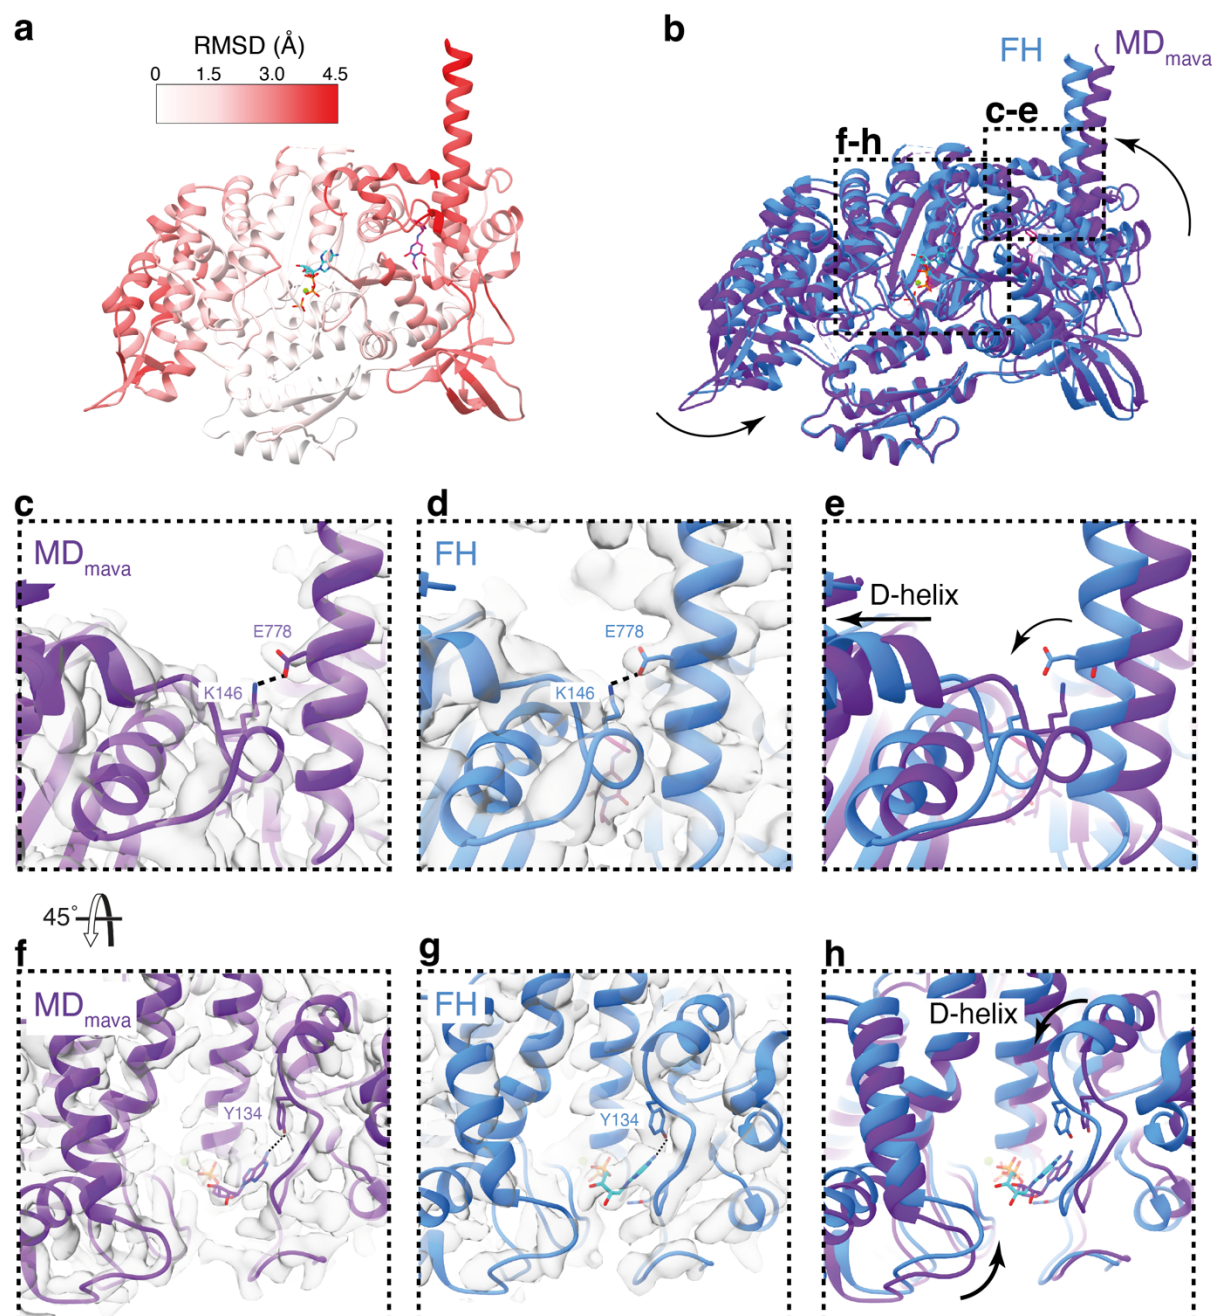

Figure 5. Mavacamten further inactivates the IHM free head. (a) RMSD comparison between MD_{mava} and IHM_{mava} FH aligned on the L50, coloured on IHM_{mava} FH model. (b) Overlay of MD_{mava} and IHM_{mava} FH blue highlighting domain movements. (c-e) Structural comparison of lever and D-helix conformation showing E778-K146 coupling hydrogen bond. (c) MD_{mava} model and cryoEM map (contour: 0.9), (d) IHM_{mava} FH model and cryoEM map (contour: 0.15) and (e) model overlay coloured as in (b). (f-H) Structural comparison of active site. (f) MD_{mava} model and cryoEM map (contour: 0.9), (g) IHM_{mava} FH model and cryoEM map (contour: 0.15) and (h) model overlay coloured as in (b).

427

428   Within the IHM_{mava} structure, the BH is further restrained by its interaction with S2 (Fig.

429   6). S2 predominantly interacts with the BH via the FH heavy chain directly

430   strengthening the interaction between the two chains (Fig. 6a). The contact interfaces

431   are predominantly charged interactions and can be split into three main regions on the

432   BH motor; the OH loop, W-helix and HLH (Fig. 6b-f; Supplementary Movie. 3).

433   The S2 in our IHM_{mava} structure adopts a curved conformation more closely resembling

434   that observed in the thick filament structures[13,14,31] over the previous single particle

435   report of IHM[40] (Extended Data Fig. 10). This is unlikely to be an effect of mavacamten,

436   but rather due to our use of a construct containing a native cHMM S2 domain

437   sequence compared to that used to determine the prior IHM[40] structure, which had a

438   short S2 sequence, ending at K942, followed by a leucine zipper[40].

439   Examination of the S2-BH interface in our IHM_{mava} structure shows that it contains

440   many more HCM mutation sites (R435C,H,S,L[41-44], R660N[45], R652G[46], K903K/G[47,48],

441   I909M[49], I913K[50]) in addition to those previously reported in the IHM[40] (K450E/T[51,52],

442   Q882E[53], Q892K[54]). Thus, maintenance of this interface is likely crucial to regulate

443   force production during cardiac contractions.
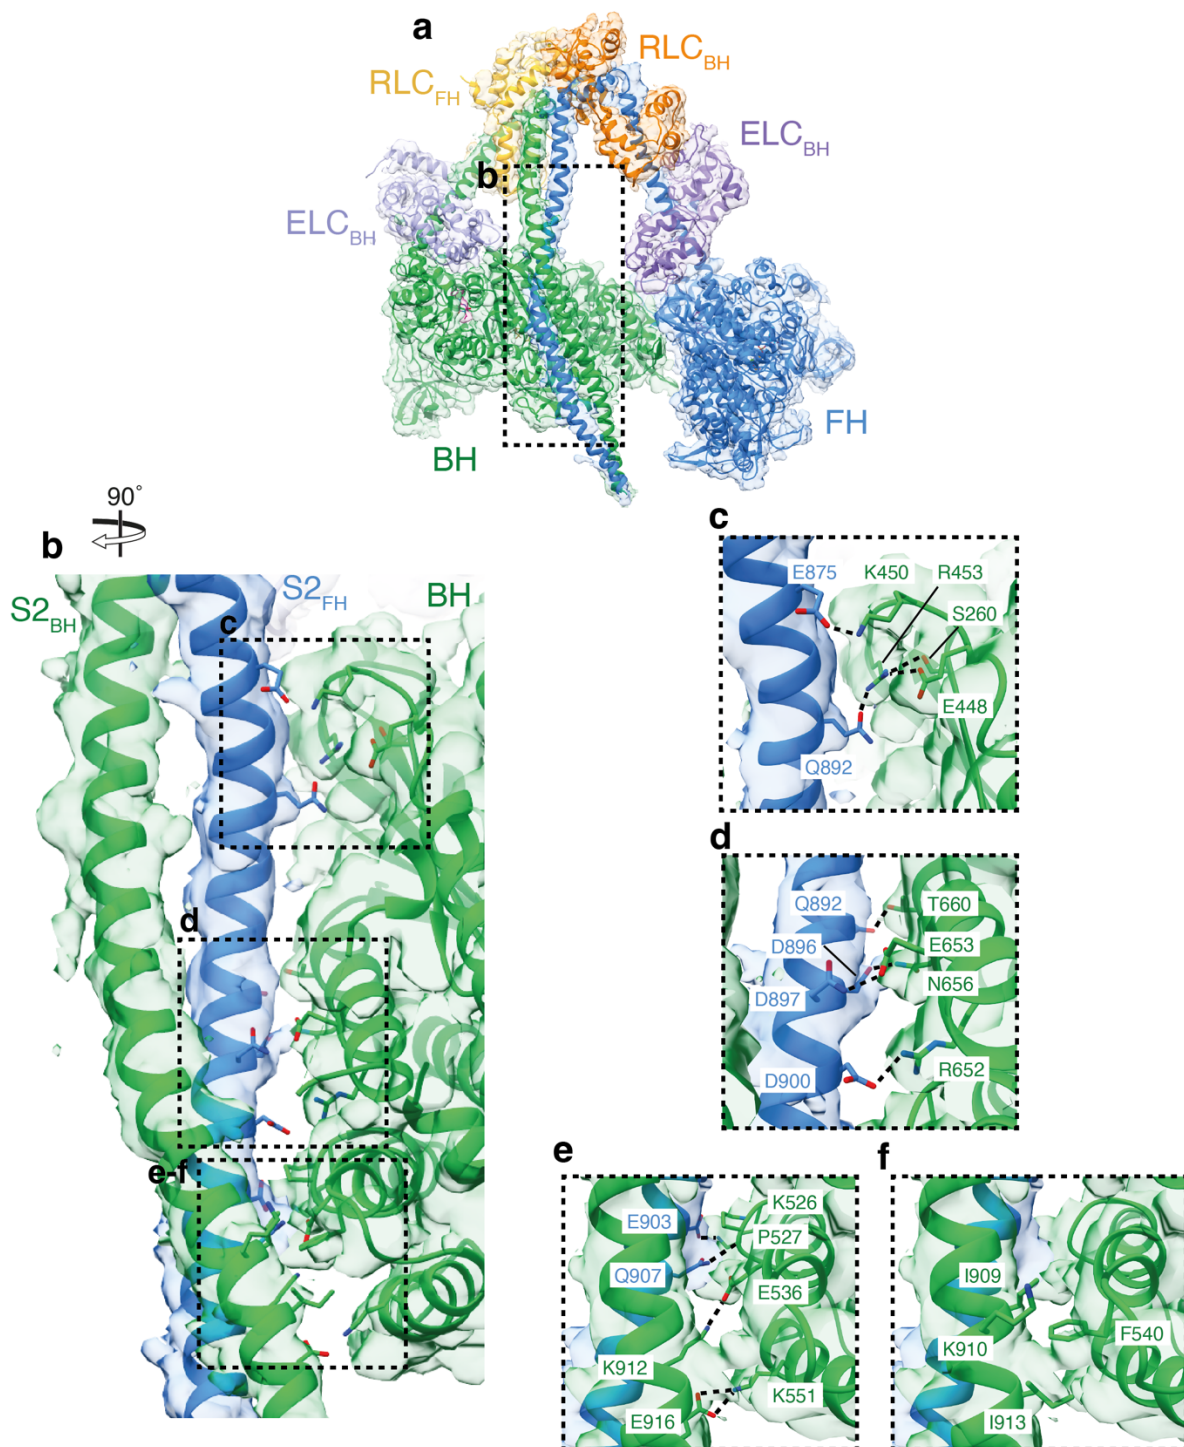

Figure 6. IHM$_{mava}$ S2 novel interactions. (a) IHM$_{mava}$ model in segmented cryoEM map coloured by chain (contour: 0.02): blocked head green, free head blue, blocked head ELC light purple, free head ELC purple, blocked head RLC yellow, free head RLC orange, mavacamten burgundy and the nucleotide in light blue. (b) Overview of IHM$_{mava}$ S2-BH interactions (modelled utilising molecular dynamics in ISOLDE) in segmented cryoEM map (contour 0.01) BH green, FH blue. (c) S2-HO linker hydrogen bonding: E875$_{FH}$-K450$_{BH}$, Q892$_{FH}$-R453$_{BH}$ and R453$_{BH}$-E448$_{BH}$. (d) S2-W helix hydrogen bonding: Q892$_{FH}$-T660$_{BH}$, D896$_{FH}$-N656$_{BH}$, D897$_{FH}$-N653$_{BH}$ and D900$_{FH}$-R652$_{BH}$. (e-f) S2-HLH interactions (e) hydrogen bonding: E903$_{FH}$-P527$_{BH}$ backbone, Q907$_{FH}$-K526$_{BH}$, K912$_{BH}$-E536$_{BH}$ and E916$_{BH}$-K551$_{BH}$ (f) hydrophobic interactions: I909$_{BH}$, I913$_{BH}$ F450$_{BH}$, and the aliphatic side chain backbone of K910$_{BH}$.

455

Discussion

456

457 In this work we have shown three high resolution cryoEM structures, two cHMM motor

458 domains with and without mavacamten bound, alongside the cHMM IHM in complex

459 with mavacamten, containing the native substrate ADP.Pi. The open head cHMM

460 motor domain structures in combination with our qXL-MS analysis and the new

461 understanding of actin activation[18], allow us to present a new mechanism through

462 which mavacamten elicits its effect on the myosin mechanochemical cycle (Fig. 7).

463 Primed motors show lever and cleft dynamics that allow them to undergo basal

464 ATPase activity (Fig. 7a) and weakly associate with actin. This can be regulated by

465 sequestration of myosin molecules into the IHM, which significantly reduces ATPase

466 activity (Fig. 7b). Upon weak binding of myosin to actin (Fig. 7c), cleft closure, Pi

467 release and powerstroke are accelerated, resulting in post-powerstroke actomyosin

468 (Fig. 7d). Mavacamten stalls motor force generation by restraining lever position and

469 inducing structural changes that stabilise ADP.Pi binding and limit cleft dynamics (Fig

470 7e). This in turn increases the abundance of the IHM by strengthening interactions at

471 the motor-motor interface (Fig. 7f). We find no evidence to support the proposal that

472 mavacamten destabilises the L50 to prohibit myosin weakly binding to actin[32]. Instead,

473 in disordered relaxed motors that can weakly associate with actin (Fig. 7g), we

474 propose that mavacamten stabilises ADP.Pi binding and reduces actin-binding cleft

475 dynamics to limit cleft closure. This inhibits the weak-to-strong actin binding transition

476 that is required for progression through the mechanochemical cycle (Fig. 7h).
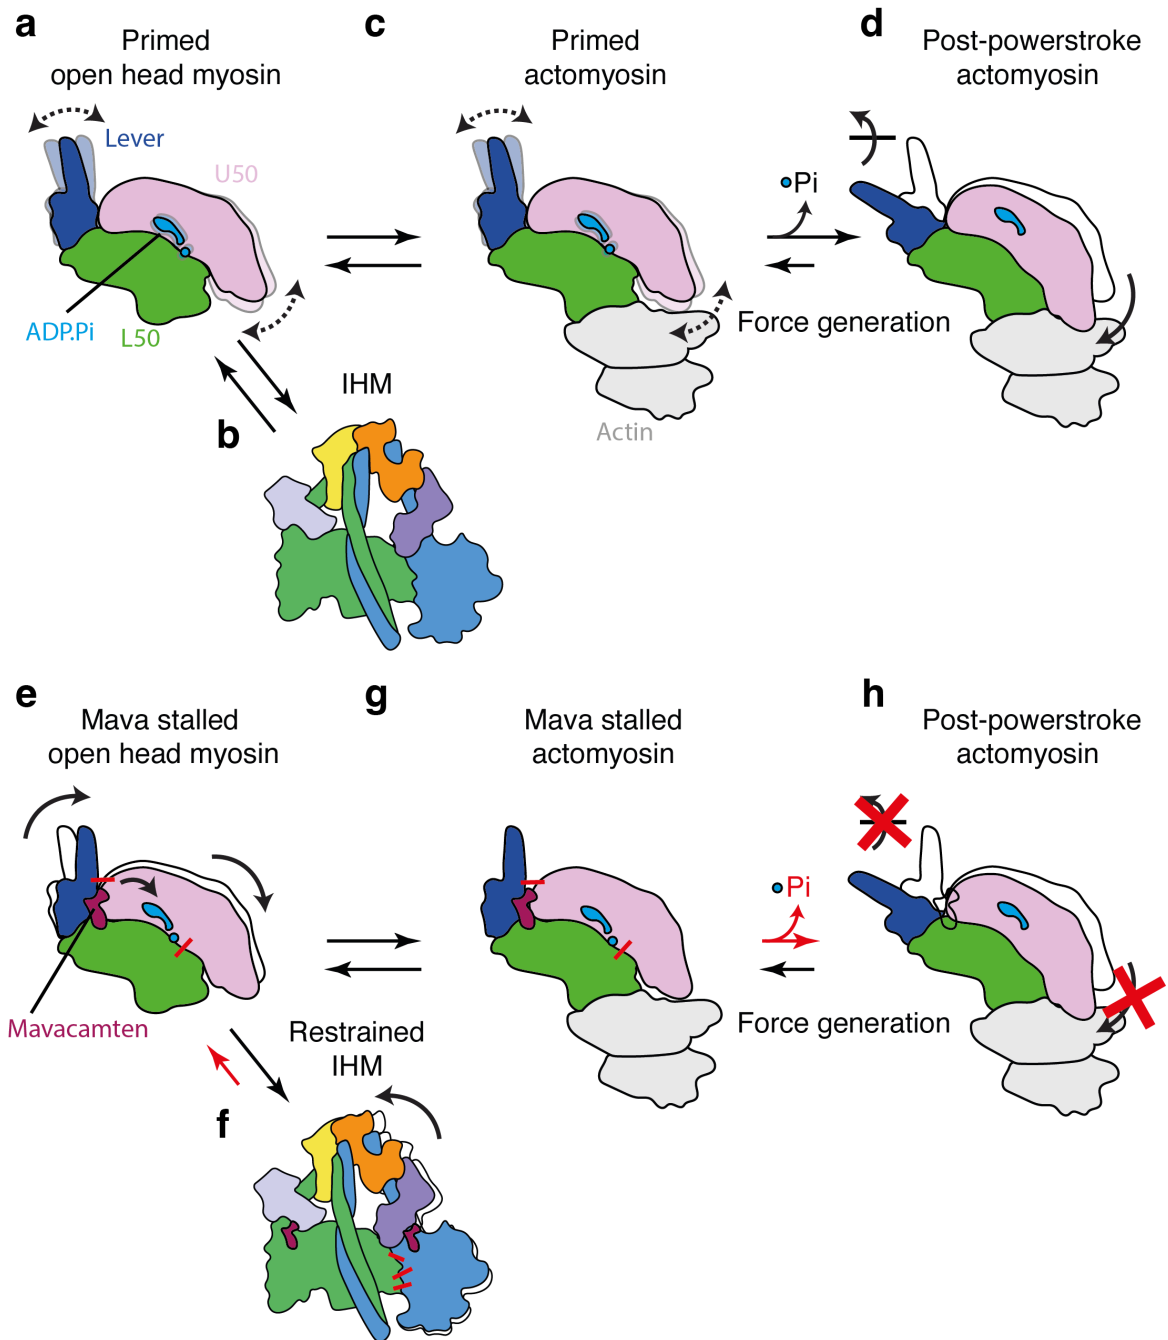

Figure 7. Overview of myosin force generation and mavacamten's structural mechanism. (a-d) Schematic representation of βCM force generation: (a) Primed open head motor with both the lever and U50 dynamically exploring conformations able to transition to (b) the IHM preventing further force generation or (c) primed actomyosin. The primed actomyosin is initially weakly-bound but rapidly proceeds through the weak-to-strong actin binding transition, releasing phosphate and undergoing the force generating powerstroke resulting in formation of (d) post-powerstroke actomyosin. (e-h) Schematic representation of βCM force generation in the presence of mavacamten: (a) Mavacamten stalled open head motor with restrained lever and shifted U50 stabilising the Pi able to transition to (f) the restrained IHM, stabilised by increased motor-motor interactions. Mava stalled open head myosin may also interact with actin forming (g) stalled actomyosin. The stalled actomyosin does not readily undergo cleft closure (red-X) preventing phosphate release and its transition through lever swing (red-X) to (h) post-powerstroke actomyosin.

491 With deeper insight into the impact of mavacamten on motor mechanics, future work
492 can begin to apply this in a clinically meaningful setting. The exploration of HCM
493 mutations in the mavacamten binding site and key interfaces created by mavacamten
494 will provide insight into the functional effects of the drug in patients with specific
495 mutations. For example, the HCM mutations R712L and E774V would directly affect
496 the mavacamten binding site likely rendering mavacamten less effective in patients
497 with these mutations[55]. The HCM mutations R719W and R723G, within immediate
498 proximity of the binding site, do mildly affect mavacamten binding[28,55].

499 The newly formed network of motor-motor interactions in the presence of mavacamten
500 also harbour several sites of pathogenic mutations: D382N[56], K383V[57], A393V[58],
501 R719W[59], R719Q[60], R719P[61], Q734P[52] and Q734E[62] . The presence of one of these
502 mutations may lessen the effectiveness of mavacamten by reducing its IHM stabilising
503 effects. Thus, further work is required to ascertain the effectiveness of mavacamten in
504 the presence of disease-causing mutations within and surrounding the mavacamten
505 binding site and at IHM contact interfaces. A deeper understanding of the mechanism
506 through which mavacamten inhibits motor function in the context of disease may
507 potentially allow us to predict patients who would be non-responders or who would
508 potentially suffer unintended side effects from treatment with mavacamten, such as a
509 significant reduction in systolic function. This would provide a path forward for
510 personalised medicine alongside the development of more effective therapeutics.

511

512 **Methods**
513 *Adenovirus manipulation*

514 The human β-cardiac HMM (cHMM) used for cryoEM encodes residues 1-1137 of the
515 *MYH7* gene (GenBank: AAA51837.1). This design includes 42 heptad repeats of the
516 S2 domain with a FLAG tag added at the C-terminus (1138-1146) (Extended Data Fig.
517 2) and has been extensively analyzed[55,63]. A revised design was used for antibody
518 capture for the motility assay that incorporates an epitope for an anti-S2 mAb
519 (10F12.3)[64]. The antibody recognizes an epitope 'AEKH RADLSRE' spanning heptads
520 43 and 44 of MYH7. The epitope was added into coiled-coil S2 domain of β-cHMM
521 followed by one additional heptad (45 heptads) and a FLAG tag at the C-terminus. The
522 single-headed cS1 design encodes residues 1-834 MYH7 followed by a short linker
523 fused to a GFP domain and a FLAG tag at the C-terminus. The expression cassette
524 includes two IRES sequences for co-expression of human MYL3 (vLC1) and MYL2

525 (vLC2). The DNA sequences were assembled, inserted into an AdEasy shuttle vector,

526 and sequenced (GeneWiz, Azenta Life Sciences, South Plainfield, NJ). Adenovirus

527 plasmids were generated by recombination in E. coli strain BJ5183-Ad1 and the

528 transgene inserts in the plasmids were sequenced. New viruses were packaged and

529 amplified in Ad293 cells through five passages to produce high titer virus stocks[65]. The

530 virus was harvested and purified by CsCl density gradient sedimentation yielding final

531 virus titers of ~10^{11} infectious units per mL (IU·mL^{-1}) for infection of C2C12 cells and

532 protein production.

533

534 *Muscle cell expression and purification of β-cardiac HMM and S1*

535 Maintenance of the mouse myogenic cell line, C2C12 (CRL 1772; American Type

536 Culture Collection, Rockville, MD), has been described in detail elsewhere[66].

537 Confluent C2C12 myoblasts were infected with replication defective recombinant

538 adenovirus (AdcHMM2.0) at 2.7 X 10^8 IU·mL^{-1} in fusion medium (89% DMEM, 10%

539 horse serum, 1% FBS). Expression of recombinant myosin (cHMM or cS1) was

540 monitored by accumulation of co-expressed GFP fluorescence in infected cells.

541 Myocyte differentiation and GFP accumulation were monitored until the cells were

542 harvested (198 – 264 hr). Cells were chilled, media removed, and the cell layer was

543 rinsed with cold PBS. The cell layer was scraped into Triton extraction buffer: 100 mM

544 NaCl, 0.5% Triton X-100, 10 mM Imidazole pH 7.0, 1 mM DTT, 5 mM MgATP, and

545 protease inhibitor cocktail (Sigma-Aldrich, St. Louis). The cell suspension was

546 collected in an ice-cold Dounce homogenizer and lysed with 15 strokes of the tight

547 pestle. The cell debris in the whole cell lysate was pelleted by centrifugation at 17,000

548 x g for 15 min at 4°C. The Triton soluble extract was fractionated by ammonium sulfate

549 precipitation using sequential steps of 0-30% saturation and 30-60% saturation. The

550 myosin precipitates between 30-60% saturation of ammonium sulfate. The recovered

551 pellet was dissolved in and dialyzed against 50 mM Tris, 150 mM NaCl, pH 7.4, 0.5

552 mM MgATP for affinity purification of the FLAG-tagged myosin on M2 mAb-Sepharose

553 beads (Sigma-Aldrich). Bound myosin was eluted with 0.1 mg·mL^{-1} FLAG peptide

554 (Sigma-Aldrich). Protein was concentrated and buffer exchanged on Amicon Ultracel-

555 10K centrifugal filters (Millipore; Darmstadt, Germany), dialyzed exhaustively into 10

556 mM MOPS, 100 mM KCl, 1 mM DTT before a final centrifugation at 300,000 x g for 10

557 min at 4°C. Aliquots were drop frozen in liquid nitrogen and stored in vapor phase at –

558   147°C. The sequence of the β-cHMM and cS1 preparations used in this study were

559   confirmed by LC-MS/MS of protein digests. Bound light chains are those that are

560   constitutively expressed in the C2C12 cells (MLC1/MLC3 and rLC2) or co-expressed

561   with the cS1gfp (vLC1 and vLC2).

562

563   *In vitro motility assay*

564   Measurement of in vitro motility of the S2 epitope tagged cHMM was done as

565   previously described for skeletal muscle myosin[64,67]. Nitrocellulose-coated glass

566   coverslips were incubated with 0.1 mg/mL of the anti-S2 mAb, 10F12.3, in PBS

567   followed by blocking the surface with 1% BSA/PBS. The cS1gfp was tethered with the

568   anti-GFP mAb 3E6 (Invitrogen, ThermoFisher) bound to nitrocellulose-coated glass

569   coverslips. The β-cHMM and cS1 proteins were diluted to 20 μg/mL in motility buffer

570   (MB) (25 mM imidazole, pH 7.8, 25 mM KCl, 4 mM $MgCl_2$, 1 mM MgATP, 1 mM DTT)

571   supplemented with 1% BSA (MB/BSA). The antibody-coated coverslips were

572   incubated with the proteins for 2 hr in a humidified chamber at 4 °C. The coverslips

573   were washed sequentially with MB/BSA and 3-times with MB before blocking with 0.5

574   μM unlabelled F-actin (5 min) and two final washes with MB. The coverslips were

575   mounted on a 15-μL drop of 2 nM rhodamine-phalloidin–labelled actin in a modified

576   motility buffer (with 7.6 mM MgATP, 50 mM DTT, 0.5% methyl cellulose, 0.1 mg/mL

577   glucose oxidase, 0.018 mg/mL catalase, 2.3 mg/mL glucose) in a small parafilm ring

578   fixed on an alumina slide with vacuum grease. The chamber is observed with a

579   temperature-controlled stage and objective set at 32 °C on an upright microscope with

580   an image-intensified CCD camera capturing images to an acquisition computer at 5–

581   30 fps depending on assay parameters. Movement of actin filaments in 2–3 fields/slide

582   for 500 frames/field of continuous imaging were captured and analyzed with

583   semiautomated filament tracking programs as previously described[67]. The trajectory

584   of every filament with a lifetime of at least 10 frames is determined; the instantaneous

585   velocity of the filament moving along the trajectory, the filament length, the distance of

586   continuous motion and the duration of pauses are tabulated. A weighted probability of

587   the actin filament velocity for hundreds of events is fit to a Gaussian distribution and

588   reported as a mean velocity and SD for each experimental condition.

589

590

591   *Negative stain head counting analysis*

592   cHMM was first prepared by crosslinking with bis(sulfosuccinimidyl)suberate (BS3) for

593   30 minutes at 25 °C in the following conditions: 2 µM cHMM, 50 µM mavacamten (5

594   % DMSO), 1 mM BS3, 1 mM EGTA, 1 mM ATP, 2 mM $MgCl_2$, 56 mM KCl, 10 mM

595   MOPS pH 7.2. The reaction was then quenched with a 100 mM final concentration of

596   Tris pH 8 preventing further crosslinking. Crosslinking was confirmed by SDS-PAGE

597   analysis (Supplementary Fig. 3).

598   Negative stain grids were prepared using the flicking method[68] by applying 5 µl of

599   crosslinked cHMM diluted 5-fold in buffer to a negative stain grid (produced in-house)

600   glow discharged for 30s (PELCO easiGlow™) prior to use. The excess HMM was then

601   flicked off and a drop of 2 % uranyl acetate applied. The excess was again flicked off

602   and the addition of a 2 % uranyl acetate drop repeated four times. Finally, the grid was

603   blotted with Whatman no. 42 Ashless filter paper and dried. Negative stain image

604   collection was performed using the FEI Tecan F20 equipped with a FEI CETA (CMOS

605   CCD). Images were collected at 29,000x magnification at a defocus of -1 to -3 µm.

606   Images were double blinded prior to counting of open and IHM-like particles. Images

607   were only included in the analysis if a minimum of 250 particles were detected within

608   the image such that the sample size was sufficient to obtain 80 % power with a 95 %

609   confidence interval. Data was then plotted into box plots and the significance in change

610   between populations was calculated using a two-tailed student t-test in GraphPad

611   Prism.

612

613   *CryoEM grid preparation and data collection*

614   Prior to cryoEM grid preparation cHMM was crosslinked with BS3 using the same

615   protocol as for negative stain with altered buffer conditions: 2 µM cHMM, 50 µM

616   mavacamten (5 % DMSO), 1 mM BS3, 1 mM EGTA, 1 mM ATP, 2 mM $MgCl_2$, 50 mM

617   KCl, 10 mM MOPS pH 7. Grids were prepared using the Vitrobot Mark IV (Thermo

618   Fisher). 3µl of the BS3 crosslinked cHMM diluted 2-fold in buffer was applied to an

619   UltrAuFoil™R 1.2/1.3 300 mesh gold grid (Quantifoil) for motor domain reconstruction

620   and a UC-A on Lacey 400 mesh Cu continuous carbon grid (Agar scientific) for IHM

621   reconstruction, glow discharged for 30 seconds at 10 mA prior to use (PELCO

622   easiGlow™). Grids were then blotted with Whatman no. 42 Ashless filter paper (Agar

623   Scientific, UK) for 1s with a force of 6, and wait time of 2s at 8 °C and 95 % humidity

624   before vitrification in liquid ethane. Data was collected on a FEI Titan Krios (Astbury

625   Biostructure Laboratory, University of Leeds) operating at 300 kV equipped with a

626   Falcon 4 direct electron camera with a specimen pixel size of 0.82 Å. Micrographs

627   were collected using EPU acquisition software at 96,000x magnification with a total

628   dose of 43e$^-$/Å^2 and a defocus range of -1.2 to -3.0 μm. Total micrographs for each

629   reconstruction were: MD 9,948 over one session, MD$_{mava}$ 21,395 over two sessions

630   and IHM$_{mava}$ 34,287 over three sessions.

631

632   *CryoEM data processing and model building*

633   MD and MD$_{mava}$ single motor domain image processing was carried out in RELION

634   4.0[69] with subsequent processing in cryoSPARC V4.2[70]. Raw movies were imported

635   into RELION for motion correction using MotionCor2[71] and CTF estimation using

636   CTFFIND-4.1[72]. Automated particle picking was then performed using Topaz initially

637   implementing the general model then a trained Topaz[73] model on selected single motor

638   domain 2D classes, this was repeated for each dataset. Particles were extracted in a

639   box size of 360^2 pixels centred on individual motor domains. The resulting particles

640   from both collections were then combined and classified using cryosparc reference-

641   free 2D classification[70]. Classes resembling single motor domains were selected for

642   further classification. An initial model was generated using cryoSPARC's ab-initio

643   reconstruction into five classes. The resulting maps were then refined through

644   heterogeneous, homogeneous and finally non-uniform refinement[70,74] on combined

645   selected classes with a final particle stack of 88,809 MD and 200,487 MD$_{mava}$. The

646   resulting map was then sharpened using a negative B-factor automatically determined

647   by cryoSPARC and local resolution estimation was calculated in cryoSPARC[70].

648   IHM$_{mava}$ image processing followed the same pipeline except IHM 2D classes were

649   selected to train a topaz[73] model and only three ab-initio[70] classes were used for initial

650   model generation. A total of 197,869 particles contributed to the final map.

651   To interpret the cryoEM maps, atomic models for the single motor domain and IHM

652   were produced. Homology models for human βCM heavy and light chains were

653   generated using the smooth muscle myosin shutdown structure (PDBID: 67Z4)[75].

654   These models were then truncated at residue 796 (within the LCD) and flexibly fit to

655   the single motor domain density using ISOLDE[34]. Phenix real space refinement was

656   then performed followed by adjustments in Coot[76] and ISOLDE[34], this was repeated

657   until satisfied. The IHM model was then built using two MD$_{mava}$ motor domain models

658   joined to the homology modelled LCD, S2 and light chains. The model was flexibly

659   fitted into the IHM map by use of ISOLDE and refined using Phenix real space

660   refinement with final adjustments in Coot[76] and ISOLDE[34].

661

662   *qXL-MS sample preparation, measurement, data preparation and analysis*

663   Purified cS1 (25 μL, final concentration of 4 μM in 10 mM MOPS, pH 7.3, 50 mM KCl,

664   1 mM $MgCl_2$, 0.34 mM DTT, 1 mM EGTA, 1 mM ATP) was incubated with 50 mM of

665   Mavacamten or DMSO control for 30 minutes at 25 °C. DSBU (600 μM; 149 molar fold

666   excess) was added, or DMSO control, and was allowed to react for 20 minutes at 25

667   °C (final DMSO concentration of 1.6 % v/v). The reaction was quenched by the addition

668   of Tris (1 M, pH 7.3) to final concentration of 20 mM and incubation at room

669   temperature for 15 minutes. Samples were flash frozen for storage prior to digestion.

670   Crosslinking was confirmed by SDS-PAGE analysis (Supplementary Fig. 3)

671   Three replicates of both crosslinked and non-crosslinked control samples (≈14.5 μg)

672   were processed for MS analysis using S-Trap micro spin columns (Protifi) as described

673   previously[77] after which the peptides were resuspended in 5 % v/v acetonitrile/0.1 %

674   v/v formic acid. Samples, ≈10 % of the final volume of each replicate, were analyzed

675   on an Vanquish Neo LC (Thermo) coupled to an Orbitrap Eclipse mass spectrometer

676   (Thermo) in positive ion and DDA mode. Separation of peptides was performed using

677   PepMap Neo C18 trap cartridge (Thermo Fisher Scientific, 174500) before using the

678   EASY spray C18 column (Thermo Fisher Scientific, ES903). Elution of peptides from

679   the column was achieved using a gradient elution of a 7.5-42.5 % (v/v) solvent B (0.1

680   % (v/v) formic acid in acetonitrile) in solvent A (0.1 % (v/v) formic acid in water) over

681   97.5 min at 250 nl min^{-1}. The eluate was infused into the instrument using an EASY-

682   Spray nanoelectrospray ionization source.

683   An online exclusion list was generated from the MS1 measurement of a non-

684   crosslinked control sample using the AcquireX AB workflow editor (Thermo Fisher

685   Scientific application module) and was applied when performing MS analysis of the

686   crosslinked samples. The Full Scan and Deepscan methods were adapted from

687   previously reported method[77] where the 'Full scan' method that lacks an MS^2 product

688   ion scan found in the Deepscan method both were Xcalibur AcquireX AB enabled and

689   identical chromatographic parameters.

690   The .RAW MS files produced were processed directly in FragPipe (v21.1)[78], without

691   conversion to mzML, subject to a mass offset search using MSFragger (v4.0)[78] where

692   default "Mass-Offset-Common-PTMs" workflow was loaded and amended. False

693   discovery rate (FDR) at the protein/peptide/ion level was set to 1 % and tolerances for

694   precursors/fragments set to 10 ppm. The generated calibrated MZML files were then

695   taken forward as the generated interact.pep.xml file.

696   MeroX (v2.0.1.4) was used to search the replicate files individually for crosslinks and

697   monolinks (from residues K,S,T and Y) against FASTA files for the S1GFP construct

698   and associated LCs, as used for the MSfragger search, without the appended decoys

699   and common contaminants from MSfragger, with a 1.0 % FDR and 50 score cutoff.

700   Precursor and fragment ion precision was set to 10 ppm with a 2.0 signal to noise

701   ratio. A single reporter ion fragment was allowed to be missing in the database search.

702   Dead-end crosslinks were allowed to react with Tris as well as allowing intrapeptide

703   crosslinks and the neutral loss of C_4H_7NO.

704   The software package Skyline[79] (MacCoss Lab Software, v23.1.0.455) was used to

705   quantify the crosslinks and monolinks found by MeroX using a modified process laid

706   out by Chen and Rappsiliber[37] and since improved by Sinz[80] and separately by Jaing

707   et al[81]. The six replicate MeroX search result .ZHRM files results were converted to

708   the ProXL XML files (https://github.com/yeastrc/proxl-import-merox).

709   All crosslinks and monolink peptides were manually curated and all peaks of all

710   transitions were manually inspected and aligned in Skyline. Crosslinks and monolinks

711   were kept for quantitation if at least two of the replicates had convincing MS2

712   assignment in MeroX (spectral matched scored over 125 and near complete MS2 peak

713   identification), and all three of the DMSO or Mavacamten replicates had well defined

714   MS1 peaks with matching retention times and strong Skyline MS2 signal. Further to

715   this, cross- or mono-links with peptides where DSBU is potentially labelled on different

716   residues but the assignment or resolution of the peaks poor were determined by cross-

717   referencing the MeroX annotated MS2 spectrum with the Skyline MS2 transitions. In

718   some cases, where the baseline separation of the peaks was good but where no clear

719   determination could be made, the highest scoring option within MeroX (annotated MS2

720   spectrum) was used and all MS1 signals were assigned to this assignment.

721   The signal intensity for each peptide for each replicate was normalised, as described

722   by Chen and Rappsiliber[37], using the total non-DSBU reacted signal intensity of each

723   replicate. The interact.pep.xml file from the MSfragger search was used to import the

724   search of the six replicates into a separate Skyline file. Monolink signal intensity was

725   combined from peptides that contain the same monolinked residue regardless of

726 peptide charge state or length. Similarly, crosslink signal intensity was combined from

727 dipeptides that bear the same residue to residue crosslink.

728 An aligned interpeptide crosslink, intrapeptide crosslink or monolink was determined

729 to have changed significantly in the presence or absence of Mavacamten by

730 conducting pairwise comparisons via a single tailed, homoscedastic t-test using

731 relative signal intensity (Supplementary Material 2). The significance was measured

732 by protein fold changes >2 and $p < 0.05$.

733

734 *Data availability*

735 The electron density maps and atomic models for MD, MD_{mava} and IHM_{mava} have been

736 deposited into EMDB, with accession codes EMD-51721, EMD-51720 and EMD-

737 51719, and the PDB files with accession codes 9GZ3, 9GZ2 and 9GZ1, respectively.

738 The XL-MS dataset generated in this study, including experimental settings and XL

739 identification results, has been deposited to the ProteomeXchange Consortium via the

740 PRIDE[82] partner repository with the dataset identifier PXD059316.

741 The following models were used for comparison purposes in our study, Bovine S1

742 cardiac myosin in complex with mavacamten PDB ID: 8QYQ and the folded-back state

743 (IHM), PDB ID: 8ACT. In addition to the above models, the following cryoEM maps

744 were used for comparisons: the folded-back state (IHM) EMDB ID: 15353, the human

745 cardiac thick filament EMDB ID: 29726 and the human cardiac thick filament EMDB

746 ID: 40471.

Author contributions

C.A.S designed the project. B.B and D.A.W produced the beta cardiac myosin. D.A.W performed in vitro motility assay and data analysis. S.N.M performed the cryoEM grid preparation, screening, optimisation and data collection. S.N.M performed the cryoEM data processing, model building and validation. S.N.M and C.A.S performed cryoEM data analysis and interpretation. J.R.T.P performed crosslinking spectrometry preparation, data collection and data processing. J.R.T.P and C.A.S performed crosslinking spectrometry data interpretation. S.N.M performed main figure, supplementary figure and movie generation. S.N.M, J.R.T.P and C.A.S wrote the manuscript. All authors discussed the results and commented on the manuscript.

Competing Interests

The authors declare no competing interests.

Extended data figures
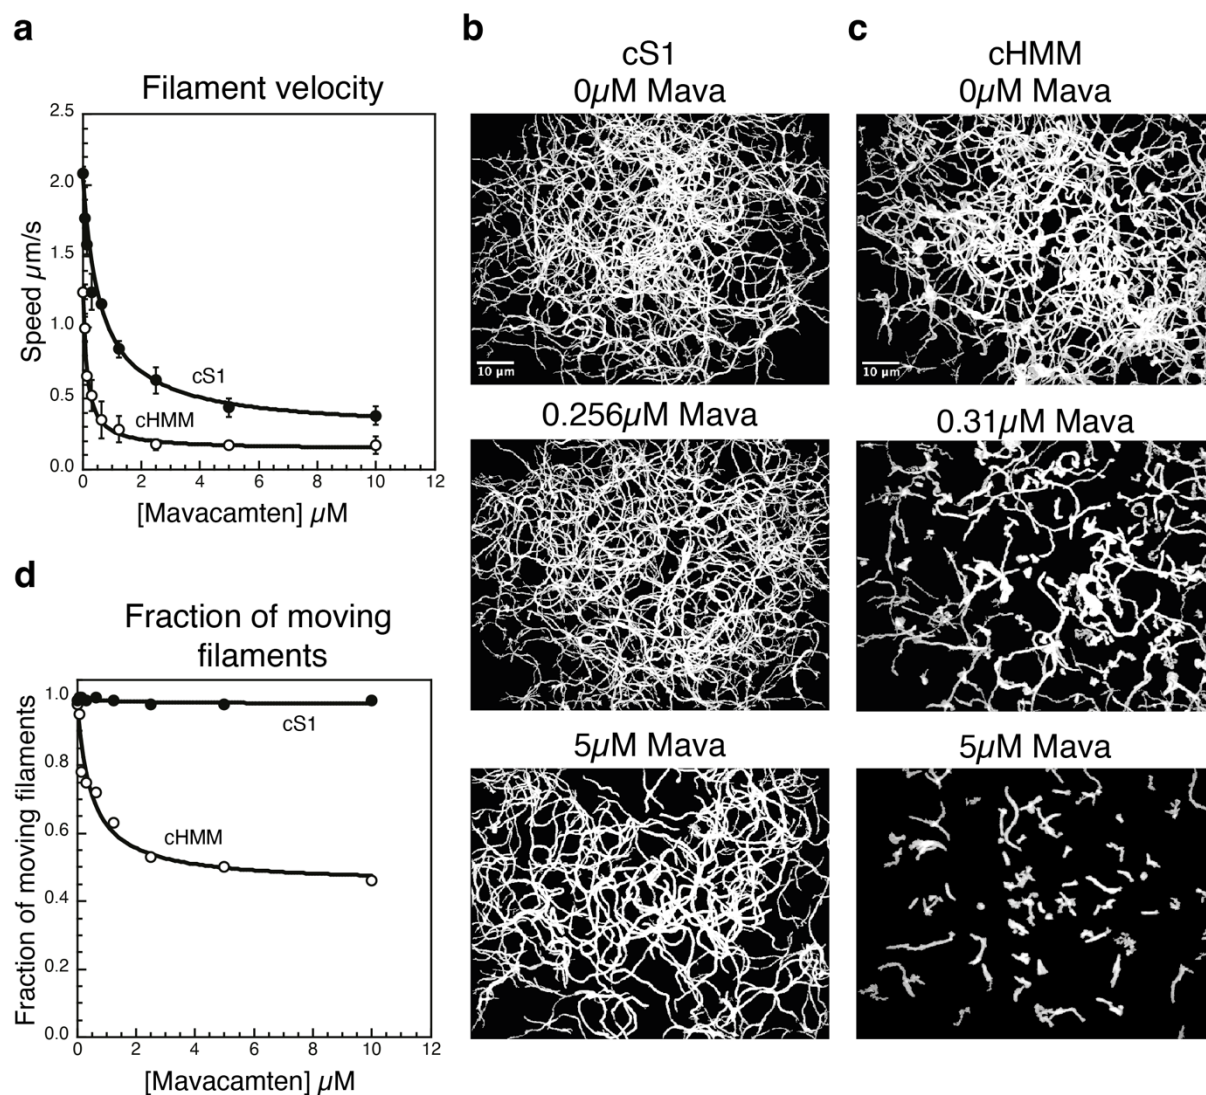

Extended Data Fig. 1. Mavacamten inhibits the gliding velocity of actin filaments more effectively for cHMM compared to cS1. (a) Actin filament gliding velocity for cS1 and cHMM over a titration of mavacamten. The filament speed powered by cS1 is slowed up to 86 % by mavacamten with an IC$_{50}$ of 0.62 μM. Comparatively, the filament speed powered by cHMM is slowed by 90 % with a 4-fold lower IC$_{50}$ of 0.14 μM. (b-c) Summed plot of actin filament movement over 100 seconds of motility for (b) cS1 and (c) cHMM at mavacamten concentrations of 0 μM, ~0.3 μM and 5 μM. (d) Analysis of the number of moving filaments for cS1 and cHMM over a titration of mavacamten. Mavacamten has no impact on the fraction of filaments moving for cS1 however, mavacamten decreases the fraction of moving filaments for cHMM in a concentration dependent manner.
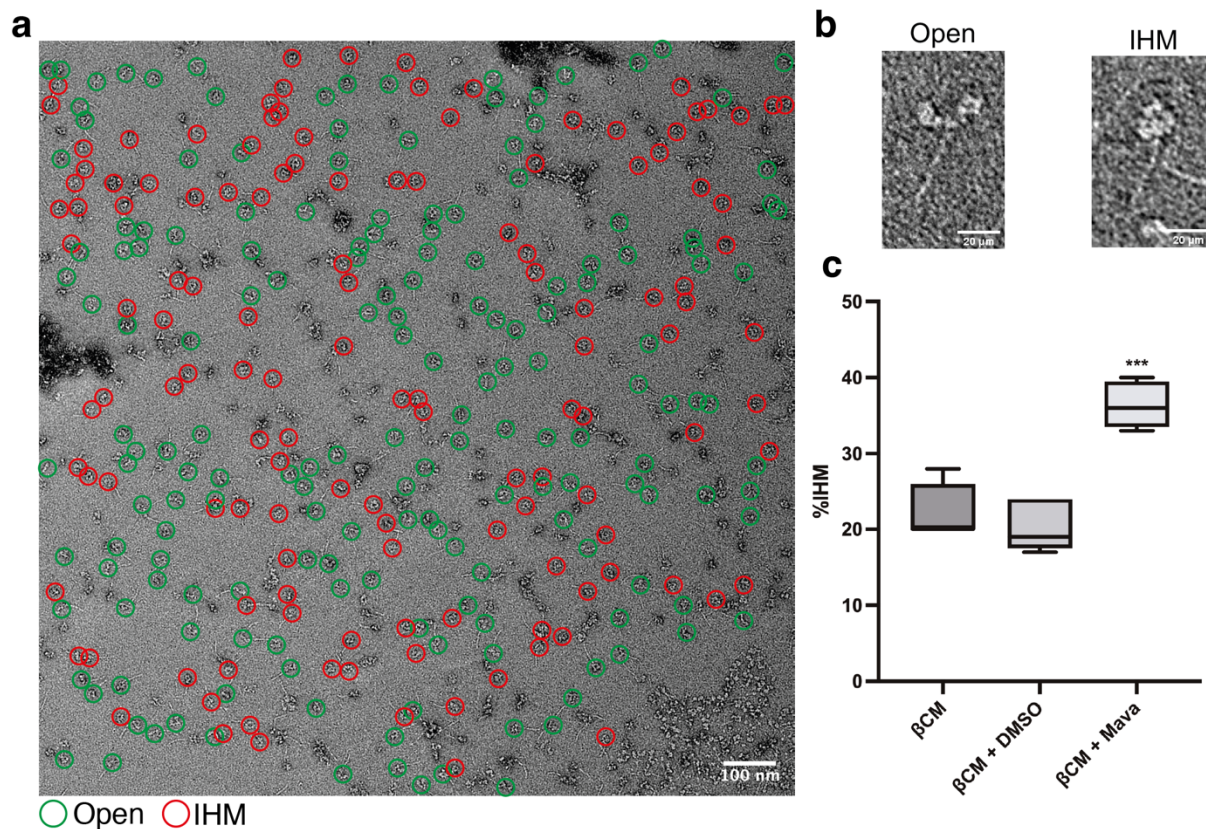

Extended Data Figure 2. Direct observation of IHM stabilisation due to mavacamten. (A) Representative negative-stain EM micrograph used during head counting assay. Counted ßCM particles highlighted by coloured circle, green: open, red: IHM. (b) Representative negative stain open and IHM ßCM molecule. (c) Box plot showing percentage of IHM over 5 biological replicates. The ßCM control resulted in a median of 20 % with a first and 3rd quartile of 20 % and 24 % respectively. ßCM containing 2.5 % v/v DMSO showed a median of 19 % with a first and third quartile of 18 % and 24 % with no significant difference to the ßCM control determined by an unpaired two-tailed student t-test. Mavacamten shows a median of 36 % with a first and third quartile of 34 % and 39 %, a significant increase in % IHM formation with a P-value of = 0.0002 determined by an unpaired two-tailed student t-test with respect to the ßCM control.

FLAG tag

Extended Data Figure 3. cHMM heavy chain sequence and sub domains (a) Key for cHMM sequence (b) cHMM heavy chain sequence highlighting resolved sub-domains and key structural regions with C-terminal flag tag.

Extended Data Figure 4. Primed motor domain cryoEM maps. (a) Segmented cryoEM map MD, split by subdomain (contour 0.5): N-terminal domain beige, L50 green, U50 pink, converter domain light blue and LCD dark blue. (b) Segmented cryoEM map of MD_{mava}, split by subdomain (contour 0.6) coloured as (a) with mavacamten in burgundy. (c-d) Magnified view of segmented cryoEM map lever displaying ELC density grey (c) MD (contour 0.3) (d) MD_{mava} (contour 0.36) (e-f) ADP.Pi fit to segmented density colured by hetroatom (c) MD (contour 0.5) (d) MD_{mava} (contour 0.6).
Extended Data Figure 5. Comparison of MD$_{mava}$ structure to bovine S1 crystal structure. (a) RMSD comparison between MD$_{mava}$ and crystal structure of bovine S1 in complex with mavacamten (burgundy) (PDB ID: 8QYQ) coloured on MD$_{mava}$ pdb (global structure alignment). (b) Overlay of lever position between MD$_{mava}$, coloured by subdomain (L50 green, U50 pink, converter domain light blue, LCD dark blue and Mavacamten in burgundy) and 8QYQ grey (global structure alignment). (c-d) Magnified view of D778 and K146 interaction in (c) MD$_{mava}$, coloured as in (b) and (d) 8QYQ grey. (e) RMSD comparison as in (a) but aligned using L50. (f) magnified view of (e) displayed as overlay of MD$_{mava}$ coloured as in (b) and 8QYQ grey showing differing U50 conformation. (g-i) Magnified view of back door residues R243, E466 as well as I478 highlighting differing conformation between (g) MD$_{mava}$ coloured as in (b) with the nucleotide in turquoise, (h) 8QYQ grey and (i) overlay.
Extended Data Figure 6. Allosteric effect of mavacamten on loop 3 hydrogen bonding (a-c) Magnified view of loop 3 hydrogen bonding network. (a) MD model green in segmented cryoEM map (contour 0.25), highlighting hydrogen bonding between D469-K572 and R567-I585 alongside D587 position. (b) MD$_{mava}$ model green in segmented cryoEM map (contour 0.42), highlighting hydrogen bonding between R567-D587 and D469, K572 position. (c) Overlay of MD gray and MD$_{mava}$ green models highlighting change in D469, K572 and D587 resulting in loss of D469-K572 interaction explaining subsequent increase in crosslinking reactivity for K572 in the presence of mavacamten.

1100
1101
1102 **Extended Data Figure 7. Change within the mavacamten binding site between**
1103 **the blocked and free head of the IHM.** (a-c) Comparison of the MD_{mava} and IHM_{mava}
1104 mavacamten binding sites shown as backbone trace with vector arrows between alpha
1105 carbons. Models were aligned on the HE helix (residues 154-168) highlighted by the
1106 dashed box. (a) MD_{mava} grey and IHM_{mava} BH green. (b) MD_{mava} grey and IHM_{mava} FH
1107 blue. (c) Overlay of panels (a-b) to highlight that the conformational change is in
1108 opposite directions for the two heads of the IHM. (d-f) Comparison of the MD and
1109 IHM_{mava} mavacamten binding sites dispayed as in (a). (d) MD grey and IHM_{mava} BH
1110 green. (e) MD grey and IHM_{mava} FH blue. (f) Overlay of (d-e). (g-h) Comparison of the
1111 IHM and IHM_{mava} mavacamten binding sites displayed as in (a). (g) IHM BH grey and
1112 IHM_{mava} BH green. (h) IHM FH grey and IHM_{mava} FH blue.
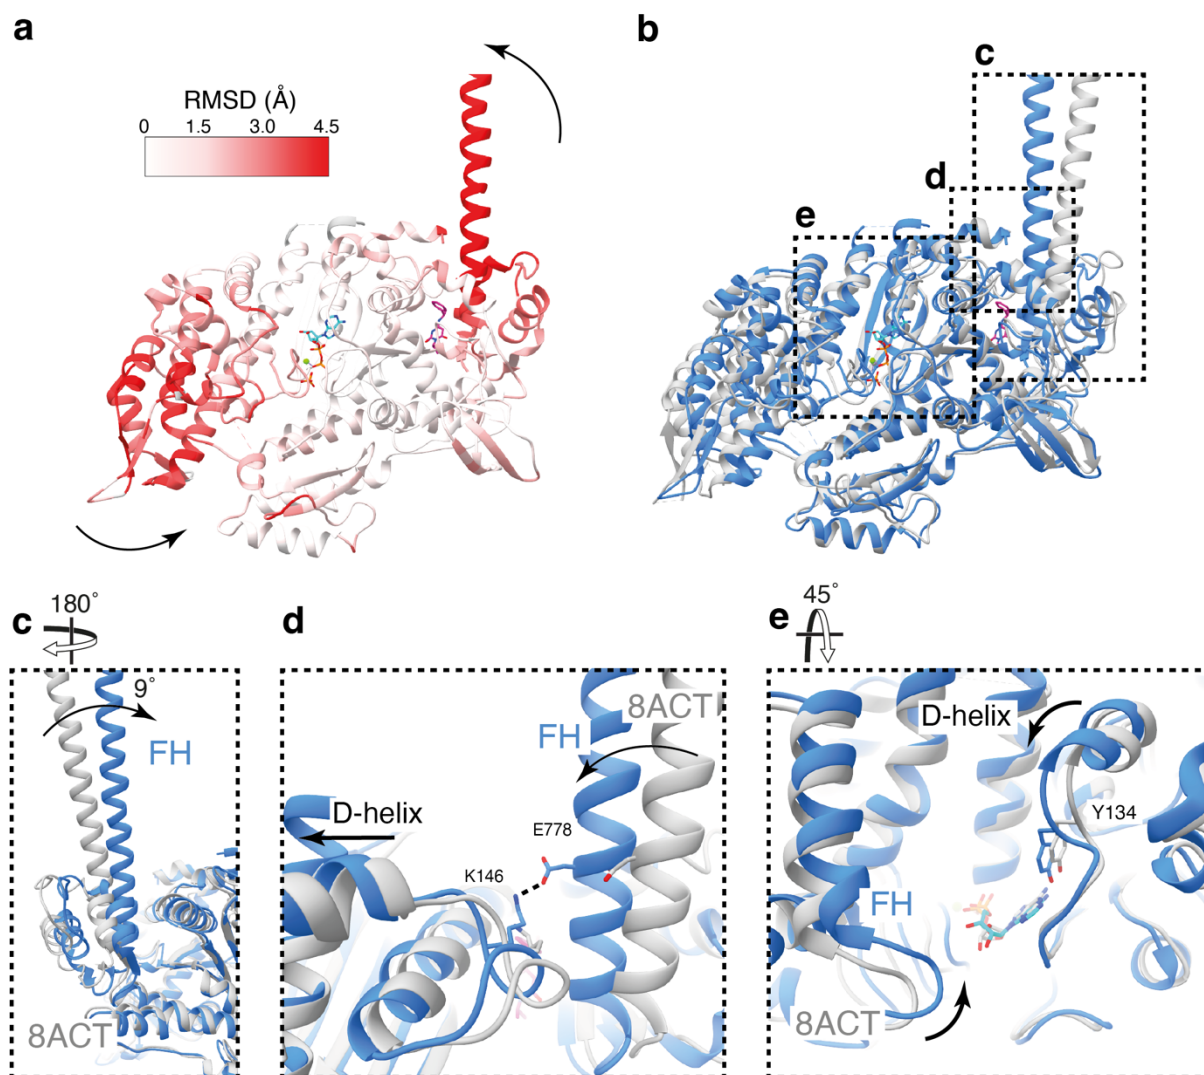

Extended Data Figure 8. FH IHM$_{mava}$ comparison to the IHM. (a) RMSD comparison between IHM$_{mava}$ FH and folded-back state FH (PDB ID: 8ACT) aligned on the L50, coloured on IHM$_{mava}$ FH model, highlighting domain movements. (b) Overlay of IHM$_{mava}$ FH blue and folded-back state FH grey. (c) Side view of the IHM$_{mava}$ FH lever overlaid on the folded-back state FH highlighting the 9° shift of the lever, coloured as in (b). (d) Structural comparison of lever and D-helix conformation showing E778-K146 coupling hydrogen bond in IHM$_{mava}$ FH but not in the folded-back state FH, coloured as in (b). (e) Structural comparison of active site highlighting loop closure around active site in IHM$_{mava}$, coloured as in (b).

1123

1124
1125 **Extended Data Figure 9. BH IHM$_{mava}$ comparison to MD$_{mava}$ and the IHM.** (a)
1126 RMSD comparison between IHM$_{mava}$ BH and MD$_{mava}$ aligned on the L50, coloured on
1127 IHM$_{mava}$ BH model (b) Overlay of IHM$_{mava}$ BH green and MD$_{mava}$ purple, highlighting
1128 U50 movement. (c) RMSD comparison between IHM$_{mava}$ BH and folded-back state BH
1129 (PDB ID: 8ACT) aligned on the L50, coloured on IHM$_{mava}$ FH model, highlighting the
1130 region the IHM$_{mava}$ S2 has the most interactions with the BH in our model. (d) Overlay
1131 of IHM$_{mava}$ BH (green) and folded-back state BH (grey), highlighting U50 movement.
1132 (e) Overlay of IHM$_{mava}$ (green/blue) and folded-back state (grey) aligned on the BH,
1133 highlighting how the change in FH lever angle changes BH U50 conformation.
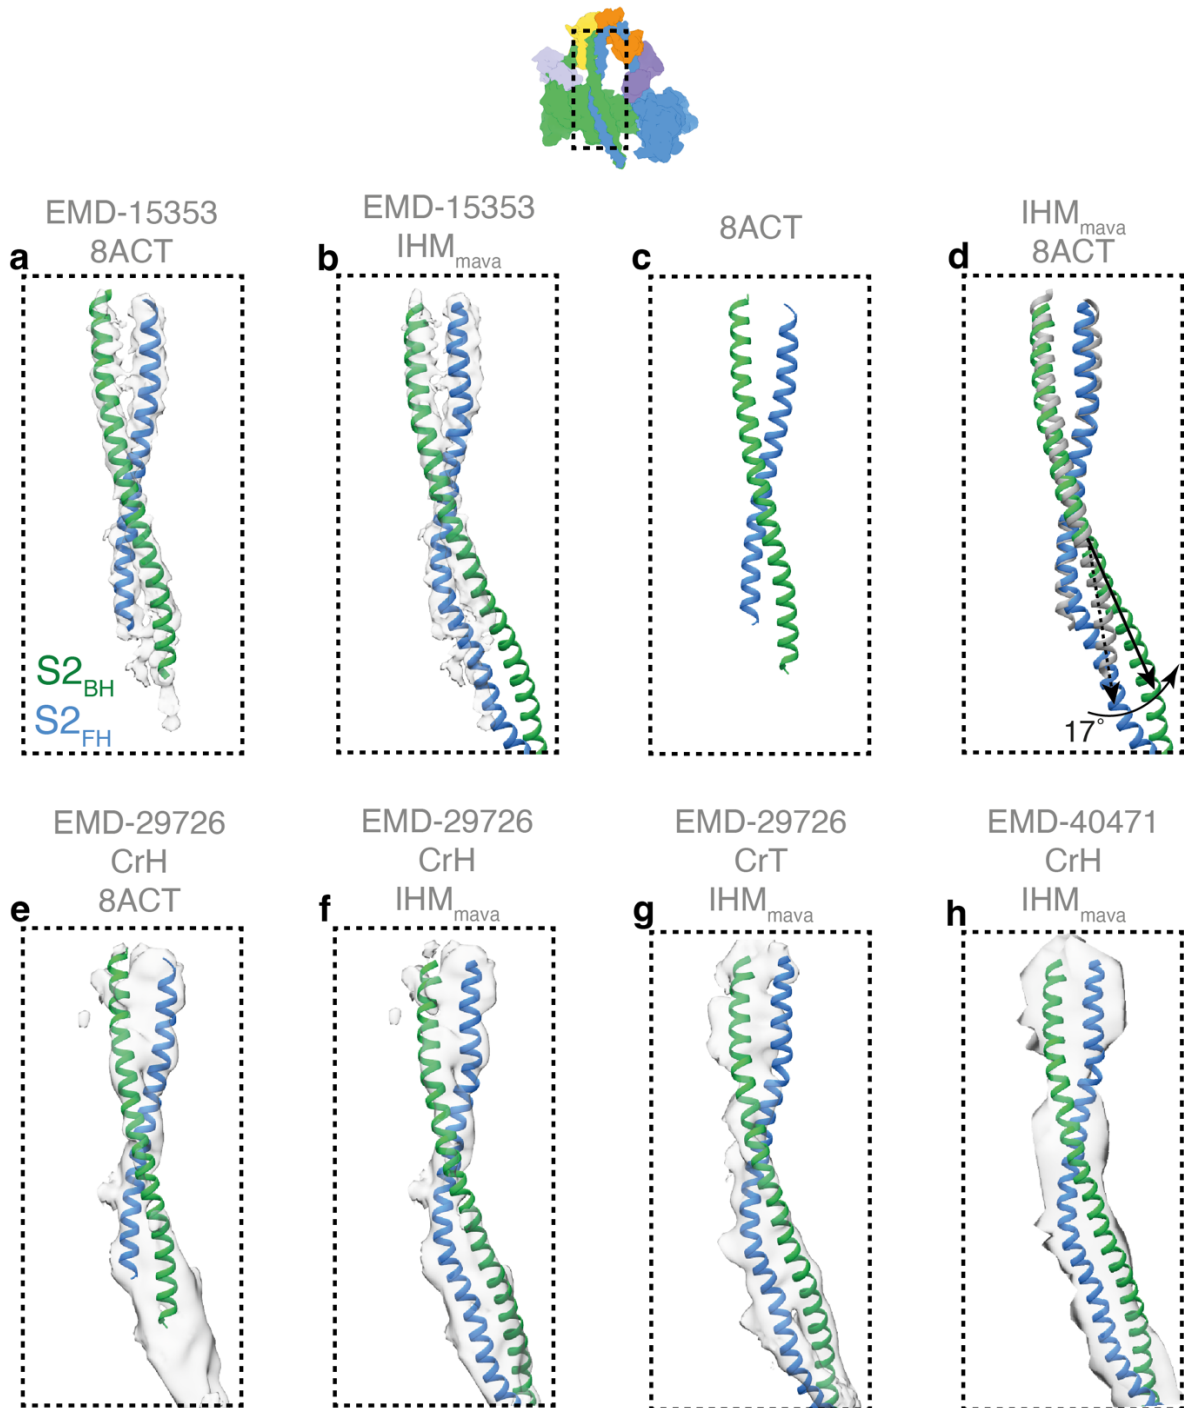

Extended Data Figure 10. IHM$_{mava}$ S2 comparison. (a-d) Comparison of S2 conformation between IHM$_{mava}$ and IHM. (a) IHM S2 PDB ID: 8ACT (green/blue) rigidly fitted into corresponding segmented map EMD-15353 (contour 0.2). (b) IHM$_{mava}$ (green/blue) rigidly fitted into segmented map EMD-15353 (contour 0.2). (c) IHM S2 model (green/blue). (d) IHM$_{mava}$ S2 model (green/blue) compared to IHM S2 model (grey) highlighting BH heavy chain angle change of 17° (measured from BH 878-905). (e) Comparison of S2 conformation between IHM and mavacamten stabilised thick filament EMD-29726 horizontal crown (CrH)(contour 0.15) (f-h) Comparison of S2 conformation between IHM$_{mava}$ and mavacamten stabilised thick filament EMD-29726 (f) horizontal crown (CrH)(contour 0.15) and (g) tilted crown (CrT)(contour 0.15).(h) Comparison of S2 conformation between IHM$_{mava}$ mavacamten free thick filament CrH EMD-40471(contour 5.0).

Supplementary Movie 1. Mavacamten reduces the number of moving filaments in cHMM and not cS1. Movie demonstrates actin gliding movment displayed as summed plots of actin filament movement over 100 seconds of motility in Fig. 1b,c. Actin gliding is shown for cHMM and cS1 +/- 5 µM mavacamten, each panel correspond to 100 sec of movement captured at 5 frames/sec. Playback is at 20 fps (4x speed) to illustrate the slow movement at 5 µM mavacamten. Without drug the actin filaments glide smoothly over both cHMM and cS1 surfaces. However, at saturating [mavacamten] (5 µM) the fraction of moving filaments for cHMM decreases and movement is often interrupted by long pauses. Comparatively, filaments continue to move smoothly over the cS1 surface with only a reduction in speed.

Supplementary Movie 2. Structural changes induced by mavacamten binding open motors. Overview of key structural changes in the motor domain induced by mavacamten binding. Model state and morph direction is shown in the top left of the movie. (0:00) Overview of MD segmented cryoEM map (contour 0.5) split by subdomain: N-terminal domain beige, L50 green, U50 pink, converter domain light blue and LCD dark blue. (0:14) 360º rotation of MD PDB in segmented map. (0:30) Fade to un split sharpened MD cryoEM map (contour 0.56) and representation of mavacamten binding. (0:35) Morph of map and pdb from MD to MD_{mava}. (0:44) Conformational changes induced by mavacamten binding, MD pdb grey and MD_{mava} pdb coloured. (0:58) 360º rotation of MD_{mava} pdb in segmented cryoEM map (contour 0.6) split by subdomain coloured as in (0:00) as well as Mavacamten in burgundy. (1:17) Magnified view of mavacamten binding site. (1:35) magnified view of LCD D-helix interaction. (1:39) Fade to un split sharpened MD_{mava} cryoEM map (contour 0.56) followed by morph of map and model from MD_{mava} to MD and back. (1:51) Highlighting conformational change at the D-helix between MD grey and MD_{mava} coloured. (2:17) Magnified view of MD_{mava} back door pdb in segmented cryoEM map shown as in (0:58). (2:20) Fade to un split sharpened MD_{mava} cryoEM map (contour 0.56) followed by morph of map and model from MD_{mava} to MD and back. (2:34) Highlighting conformational change at the back door between MD grey and MD_{mava} coloured.

Supplementary Movie 3. IHM_{mava} interaction interfaces. (0:00) Overview and 360º rotation of IHM_{mava} segmented cryoEM map coloured by chain (contour: 0.08): blocked head green, free head blue, blocked head ELC light purple, free head ELC purple, blocked head RLC yellow, free head RLC orange, mavacamten burgundy and the nucleotide in light blue. (0:31) 360º rotation of IHM_{mava} PDB in segmented cryoEM map coloured as in (0:00). (0:50) Magnified view of BH mavacamten binding site. (1:07) Magnified view of FH mavacamten binding site. (1:30) Magnified view of motor-motor interface (change in map contour to 0.01). (1:46) Magnified view of HCM $loop_{BH}$ $transducer_{FH}$ interface. (2:03) Magnified view of BH ELC_{FH} interface. (2:22) Overview of S2 BH interface highlighting the three main contact regions on the BH: OH-helix, W-helix and HLH. (2:36) Magnified view of S2 OH-$helix_{BH}$ interface. (2:49) Magnified view of S2 W-$helix_{BH}$ interface. (3:01) Magnified view of S2 HLH_{BH} interface.
