Sulfane sulfur, including  $\text{HS}_n\text{H}$  and  $\text{RS}_n\text{H}$ ,  $n \geq 2$ ;  $\text{RS}_n\text{R}$ ,  $n \geq 3$ , contains zero-valent sulfur ( $\text{S}^0$ ). It is a newly discovered cellular component with important physiological functions, including redox homeostasis maintenance and signaling [1]. Due to the diversity of sulfane sulfur species, their chemical properties are still largely unknown. We recently discovered that biologically relevant sulfane sulfur species display strong optical signals when analyzed by resonance synchronous spectroscopy ( $\text{RS}_2$ ), in which excitation and emission wavelengths are essentially identical [2]. We reported that several sulfane sulfur species, including inorganic polysulfide ( $\text{H}_2\text{S}_n$ ,  $\text{HS}_n^-$ , and  $\text{S}_n^{2-}$ ), glutathione persulfide (GSSH), protein persulfide, and organic polysulfide ( $\text{RS}_n\text{H}$ ,  $n \geq 2$  and  $\text{RS}_n\text{R}$ ,  $n \geq 3$ ) have  $\text{RS}_2$  signals, which are affected by pH if the sulfane sulfur species undergo protonation and deprotonation [2].

After our publication, Cuevasanta et al. published a commentary, claiming that  $\text{RS}_2$  does not measure soluble sulfane sulfur but elemental sulfur particles derived from soluble sulfane sulfur [3]. However, they only did two inappropriate experiments without any quantification, leading to a wrong conclusion that our method “only measures unspecific light scattering”.

For the first experiment, they showed colloidal sulfur, prepared by vortexing sulfur powder into water, also displayed  $\text{RS}_2$  signals, suggesting that our reported  $\text{RS}_2$  of sulfane sulfur is due to light scattering of sulfur particles [3]. We performed a similar experiment, diluting inorganic polysulfide (26 mM stock in an alkaline solution [4]) to 1.5  $\mu\text{M}$  in 50 mM Tris buffer (pH 7.4) for  $\text{RS}_2$  analysis. We then prepared colloidal sulfur by vortexing sulfur powder in the same buffer [3]. The suspension was allowed to settle for 1 hour, and the supernatant was diluted with equal volume of the same buffer before  $\text{RS}_2$  analysis. The data are presented as  $\text{R}_2\text{S}_2$  in which the buffer's  $\text{RS}_2$  is corrected [5]. This correction is necessary, as Tris buffer has background  $\text{RS}_2$  signals (Fig. 1A in [2]). Cuevasanta et al. used water instead of a buffer and did not use  $\text{R}_2\text{S}_2$  [3]. The  $\text{R}_2\text{S}_2$  spectra are similar but different when

compared via overlaying, as the colloidal sulfur spectrum is red-shifted (Fig. 1, black vs. blue). The  $\text{RS}_2$  signal of the polysulfide solution was unstable and mostly disappeared after 5 min (Fig. 1, black, red, green, and grey), while that of colloidal sulfur was stable, showing no reduction within 30 min (Fig. 2). Thus, the  $\text{RS}_2$  signals of polysulfide and colloidal sulfur are different.

We have showed the presence of elemental sulfur  $\text{S}_8$  in inorganic polysulfide at neutral pH [2]. Polysulfide stock is prepared in alkaline solutions with sulfide in excess under anaerobic conditions [4], and it is mainly present as long chain polysulfide species [2]. When the stock was diluted to 1.5  $\mu\text{M}$  in 50 mM Tris buffer (pH 7.4),  $\text{S}_8$  could form at the relative neutral pH [2]. To test whether  $\text{S}_8$  was mainly responsible for  $\text{RS}_2$ , we dissolved elemental sulfur in acetone (15 mM) and diluted it to 1.5  $\mu\text{M}$  in 50 mM Tris buffer (pH 7.4). The  $\text{R}_2\text{S}_2$  signal of  $\text{S}_8$  was much weaker, about 4.6-fold lower than that of 1.5  $\mu\text{M}$  inorganic polysulfide (Fig. 1, pink). Thus, when inorganic polysulfide is diluted in 50 mM Tris buffer (pH 7.4), the initial  $\text{RS}_2$  signal is mainly from the polysulfide. The rapid loss of the signal is likely due to the conversion to  $\text{S}_8$  or the oxidation by  $\text{O}_2$ . The produced  $\text{S}_8$  should aggregate into fine particles similar to that of  $\text{S}_8$ , obtained via diluting sulfur stock in acetone into the same buffer; both should display reduced  $\text{RS}_2$  signals likely because of scattering and the sulfane sulfur property of  $\text{S}_8$  (Fig. 1), as  $\text{RS}_2$  is often used to analyzed aggregates of dye molecules [5,6].

For the second experiment, Cuevasanta et al. used 1 mM  $\text{H}_2\text{O}_2$  to oxidize 1 mM  $\text{H}_2\text{S}$  and claimed that the reaction also produced the reported signal [3]. They showed that the obtained signal was from small particles via light scattering. However, they did not show how long it took to generate the signal and how much sulfur particles were generated from 1 mM  $\text{H}_2\text{S}$ . We repeated their experiment and could not detect the signal within 30 min. This is likely due to the high concentrations of  $\text{H}_2\text{O}_2$  used in their experiment. Since  $\text{H}_2\text{O}_2$  reacts with  $\text{H}_2\text{S}$  at a much slower rate ( $0.46 \text{ M}^{-1}\text{s}^{-1}$ , the 2<sup>nd</sup> rate constant [2]) than

**Fig. 2.** The  $RS_2$  of the colloidal sulfur solution (Fig. 1 legend) was stable within 30 min. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

with sulfane sulfur ( $23.76 \text{ M}^{-1}\text{s}^{-1}$  for GSSH reacting with  $\text{H}_2\text{O}_2$  [2]), the produced polysulfide is not accumulated but rapidly oxidized by  $\text{H}_2\text{O}_2$ . The method cannot be used to prepare inorganic polysulfide, which is unstable even without  $\text{H}_2\text{O}_2$  (Fig. 1). They misused our kinetic assay [3]. We used excess sulfide to react with  $50 \mu\text{M}$   $\text{H}_2\text{O}_2$  and monitored polysulfide production by using  $RS_2$ ; we only used the data from the first 3 min to obtain the initial rate, from which the rate constant

was calculated [2].

The  $R_2S_2$  spectrum of GSSH at pH 6 (Fig. 2A of original paper [2]) has a maximum around 650 nm. In comparison, the  $R_2S_2$  spectrum of colloidal sulfur in 50 mM phosphate buffer (pH 6) is essentially the same as that in 50 mM Tris buffer, pH 7.4, significantly different from that of GSSH [3]. As presented in Fig. 1C&D of our original paper [2], the  $R_2S_2$  spectra of the commercially available Bis(methyl) trisulfide ( $\text{CH}_3\text{-SSS-CH}_3$ ) and Bis[3-(triethoxysilyl)propyl] tetrasulfide are also different from that of colloidal sulfur. Thus, there is no evidence to suggest that these compounds decay to elemental sulfur during our assay. Cuevasanta et al. suggested that the reaction of these compounds with  $\text{H}_2\text{O}_2$  or SSP4 (sulfane sulfur probe 4) as we tested is through colloidal sulfur without any supporting evidence [3]. We have not found any other reports suggesting that colloidal sulfur is an intermediate in these reactions.

$RS_2$  is a data acquisition method by using a fluorometer.  $RS_2$  signals can be contributed by scattering, on-fluorescence, and possible Stokes' shifted fluorescence [6]. Further, resonant Rayleigh scattering, caused by molecular polarity, may also contribute to  $RS_2$  [7,8]. The electrophilic property of sulfane sulfur could be polar when containing a thiosulfoxide bond [2]. We did not observe any fluorescence besides  $RS_2$  signals for all tested sulfane sulfur. However, a compound does not have to be fluorescent to give  $RS_2$  signals, as evidence by the  $RS_2$  spectrum of 50 mM Tris buffer (Fig. 1A in [2]). In short, the  $RS_2$  property of sulfane sulfur is unexpected, but is real.
