ABSTRACT

Leishmania (Mundinia) martiniquensis is responsible for visceral leishmaniasis in patients with no known underlying immunodeficiency, and visceral or disseminated cutaneous leishmaniasis in HIV-infected patients. The available anti-*Leishmania* drugs for treatment have limitations such as high toxicity and variable efficacy. To improve the therapeutic index of anti-*Leishmania* drugs, the search for a new drug or a new natural compound in combination therapy instead of using monotherapy to reduce drug side effect and have high efficacy is required. In this study, anti-*Leishmania* activity of 8-hydroxyquinoline (8HQ) and its synergistic effect with amphotericin B (AmB) against *L. martiniquensis* were evaluated *in vitro* for the first time. These results showed that 8HQ presented anti-*Leishmania* activity against *L. martiniquensis* with IC_{50} 1.60 ± 0.28 and 1.56 ± 0.02 $\mu\text{g/mL}$ for promastigotes and intracellular amastigotes, respectively. The selectivity index (SI) value of 8HQ was 79.84 for promastigotes and 82.40 for intracellular amastigotes, which highlight promising results for the use of 8HQ in the treatment of *L. martiniquensis*-infected host cells. Interestingly, four combinations of 8HQ and AmB provided synergistic effects for intracellular amastigotes and showed no toxic effects to host cells. These results provided information of using a combination therapy in treating this *Leishmania* species leads to further development of therapy and can be considered as an alternative treatment for leishmaniasis.

INTRODUCTION

Leishmaniasis is an infectious disease caused by different species of the protozoan parasite of the genus *Leishmania*, which invades a host to grow inside macrophages (*Laranjeira-Silva, Hamza & Pérez-Victoria, 2020*). *Leishmania* parasites are transmitted to humans and mammals through the bite of the sandfly vector that carries the infective metacyclic

promastigotes (Giraud et al., 2019). Depending on the species of parasite, patients infected with *Leishmania* spp. may present a broad spectrum of clinical manifestations, from cutaneous (CL) to visceral leishmaniasis (VL) and be a carrier of parasites for long period with or without symptoms (Ghorbani & Farhoudi, 2017).

Both CL and VL disease are endemic in 56 and 55 countries, respectively. An estimated 50,000 to 90,000 new cases of VL and 600,000 to 1 million new cases of CL occur worldwide annually (WHO, 2021).

Leishmaniasis has been reported as emerging disease in several countries. In Southeast Asia, most of cases are infected with *Leishmania martiniquensis*, responsible for VL in a patient with no known underlying immunodeficiency, and VL or disseminated cutaneous leishmaniasis (DCL) in a HIV patient (Chusri et al., 2012; Pothirat et al., 2014). *L. martiniquensis* is of particular interest because it is in a new subgenus *L. (Mundinia)* (Espinosa et al., 2018) and few studies on drug treatment are available.

The treatment of leishmaniasis mainly relies on chemotherapy. Antimonials, miltefosine, paromomycin and amphotericin B deoxycholate (AmB) are antileishmanial drugs that have been used historically to treat a disease. However, there have been reports of antimony resistance in several regions, especially in the Indian subcontinent (Dumetz et al., 2018). Thus, miltefosine, paromomycin and AmB are increasingly used (Ponte-Sucre et al., 2017).

Most cases of *L. martiniquensis* infections were treated with AmB, since it is an available drug in many countries (Leelayoova et al., 2017). Recently, Phumee et al. (2020) using the colorimetric prestoblu resazurin-based assay, demonstrated that IC₅₀ of amphotericin B was twice increased for *L. martiniquensis* (Phumee et al., 2020). Some fluorinated rhodacyanine analogues have shown better values than AmB (IC₅₀ = 40–85 nM) against the promastigote and axenic amastigote stages (Lasing et al., 2020).

AmB is an antifungal agent, that provides reliable and broad-spectrum therapeutic alternative and also for use in the treatment of leishmaniasis. The drug causes the formation of an aqueous pore in cell membrane of the parasite, with an excellent leishmanicidal activity. However, the use of this drug is accompanied by dose-limited toxicities, highly toxic side effects, infusion-related reactions, and nephrotoxicity (Sundar & Chatterjee, 2006; Hamill, 2013). Therefore, to improve the therapeutic index of AmB, the search for a new drug or a new natural compound in combination with AmB therapy instead of using AmB in monotherapy may reduce drug side effects and have high efficacy.

8-Hydroxyquinoline (8HQ) is a plant-derived or synthetic quinoline. The compound has been used in agriculture, textile, wood and paper industries as a preservative, since it has the metal property of being a fungicidal activity (Short et al., 2006). Previous studies found that 8HQ showed great interest in a broad range of biological activities, such as antioxidant (Chobot et al., 2018), anticancer (Xie, Cai & Peng, 2018), antibacterial (Odingo et al., 2019), antifungal (Pippi et al., 2017), antiviral (Lai, Sridhar Prasad & Padmanabhan, 2013) and antischistosomal (Allam, Eweas & Abuelsaad, 2013) activities. It has been shown to have anti-*Leishmania* activity against *L. tropica*, *L. major* and *L. infantum* (Dardari et al., 2004). The compound was also effective against the intracellular stage of *L. braziliensis*, *L. amazonensis* and *L. infantum* with low toxicity to

primary cells (*Costa Duarte et al., 2016*). The 8HQN has not been tested on *L. martiniquensis*. Thus, the aims of this study were to determine the anti-*Leishmania* activity of 8HQN, followed by the investigation of the synergistic effect between 8HQN and AmB against *L. martiniquensis*. To the best of knowledge, the results provided information of using a combination therapy in treating *L. martiniquensis* infection that may be useful for future treatment.

MATERIALS AND METHODS

Compound and drug

8HQN was commercially purchased (Sigma-Aldrich, Saint Louis, MO, USA). A stock solution of 8HQN (7,500 µg/mL) was prepared in 50% (v/v) ethanol (C₂H₅OH) and stored at -20 °C. AmB (250 µg/mL) was purchased (Gibco, Grand Island, NY, USA). Various concentrations of 8HQN and AmB were prepared in the fresh medium and used immediately.

Parasites

Leishmania martiniquensis (MHOM/2013/LSCM3) was obtained from the Department of Parasitology, Faculty of Medicine, Chulalongkorn University. Promastigotes were grown in Schneider's insect medium (SIM), pH 6.8 (Sigma-Aldrich, Saint Louis, MO, USA), containing 10% (v/v) heat-inactivated fetal bovine serum (FBS) (Gibco, Grand Island, NY, USA) and 25 µg/mL gentamicin sulfate (Sigma-Aldrich, Saint Louis, MO, USA) and incubated at 26 °C. Promastigotes were maintained in a logarithmic phase of growth by sub-passage every 3–4 days, starting the cultures with 10⁶ parasites/mL.

THP-1 cells

The human monocytic cell line (THP-1) was used as a mammalian host cell for cytotoxicity assay, intracellular amastigote assay and drug combination assay. THP-1 cells were offered by Dr. Sirida Yangshim, Department of Microbiology, Faculty of Medicine, Chiang Mai University. THP-1 cells were cultured in RPMI-1640 medium (Gibco, Grand Island, NY, USA) supplemented with 10% FBS, 25 µg/mL gentamicin sulfate at 37 °C, 5%CO₂. The sub-passaged was performed every 2–3 days, starting cultures with 5 × 10⁴ cells/mL. THP-1 cells were treated with 10 ng/mL of phorbalmiristate acetate (PMA) (Sigma-Aldrich, Saint Louis, MO, USA) to induce macrophages differentiation before starting the experiment.

Promastigote assay

To determine the anti-*Leishmania* activity of 8HQN against *L. martiniquensis* promastigotes, the logarithmic phase promastigotes were cultivated in the culture medium with the presence of various concentrations of 8HQN. AmB was used as a control. Parasite viability was assessed using alamarBlue cell viability assay (Thermo Fisher Scientific, Waltham, MA, USA) as described by *Intakhan et al. (2020)*. Briefly, 8HQN (0.39–25 µg/mL) and AmB (0.004–0.625 µg/mL) were prepared in SIM supplemented with 10% FBS and 25 µg/mL gentamicin sulfate. A total of 50 µL of different dilutions of 8HQN

and AmB were plated in a 96-well culture plate (Nunc, Roskilde, Denmark) and then added with 50 μL of 2×10^6 logarithmic phase promastigotes of *L. martiniquensis*. Parasites were incubated with compound and drug at 26 °C for 48 h. To determine parasite proliferation using alamarBlue cell viability assay, 10 μL of alamarBlue reagent (Thermo Fisher Scientific, Waltham, MA, USA) was added into each well of a 96-well culture plate. The culture was further incubated for 24 h at 26 °C. Then, the absorbance was measured at wavelength of 570 and 600 nm using an Eon™ microplate spectrophotometer (BioTek, Winooski, VT, USA). Wells with medium alone and medium containing 10 μL of alamarBlue reagent were included as controls. Dose response curves obtained from % growth inhibition were generated using GraphPad Prism software (GraphPad Prism Software Inc., San Diego, CA, USA) The IC₅₀ value (concentration of the compound or drug that inhibits 50% of the parasite viability after 72 h of incubation) was determined and expressed as mean \pm SD. Results are from three independent experiments.

Cytotoxicity assay

The cytotoxic activity of 8HQN was evaluated in THP-1 cells. Cells were treated with PMA to induce differentiation towards macrophages. Briefly, THP-1 cells were prepared in RPMI-1640 medium (10% FBS and 25 $\mu\text{g}/\text{mL}$ gentamicin sulfate) containing 10 ng/mL of PMA. 100 μL of cells were placed into each well of 96-well culture plates (2.5×10^4 cells/well). PMA-treated cells were incubated at 37 °C, 5%CO₂ for 24 h to allow cell adhesion (complete differentiation). Then, cultures were washed and replaced with culture medium containing different dilutions of 8HQN (0.49–500 $\mu\text{g}/\text{mL}$), AmB (0.0049–10 $\mu\text{g}/\text{mL}$) and incubated for another 72 h at 37 °C, 5%CO₂. To determine cell viability after exposure to compound and drug using alamarBlue cell viability assay, 10 μL of alamarBlue reagent was added into each well of a 96-well culture plate. Then, the incubation was continued for 4 h at 37 °C, 5%CO₂ before reading the absorbance at wavelengths of 570 and 600 nm using an Eon™ microplate spectrophotometer. Wells with medium alone and medium containing 10 μL of alamarBlue reagent were included as controls. Dose response curves obtained from % survival of THP-1 cell were generated using GraphPad Prism software. The CC₅₀ value (concentration of compound or drug that induces 50% of cell death after an incubation period of 72 h) was determined and expressed as mean \pm SD. Results are from three independent experiments.

Preparation of *Leishmania*-infected macrophages

Promastigotes were sub-passaged into RPMI-1640 medium supplemented with 20%FBS, 25 $\mu\text{g}/\text{mL}$ gentamicin sulfate, pH 5.5 to stimulate metacyclogenesis (Zakai, Chance & Bates, 1998). Promastigotes were incubated at 26 °C for 5 days to yield metacyclic promastigotes. The culture with the presence of 70% of metacyclic promastigotes (body length < 12.5 μm , body width 1.5 μm and flagellum > body length) according to the criteria of Chanmol et al. (2019) was used for host cell infection. THP-1 cells were treated with 10 ng/mL of PMA for 24 h to differentiate into host cell macrophages in 96-well culture plates. Then, macrophages were infected with promastigotes (obtained from the culture

with 70% metacyclic promastigotes) at a parasite/macrophage ratio of 10:1 to reach an optimal level of infection and incubated at 37 °C, 5%CO₂.

Intracellular amastigote assay

To determine the anti-*Leishmania* activity of 8HQN against *L. martiniquensis* amastigotes, intracellular amastigotes in THP-1 derived macrophages were treated with various concentrations of 8HQN. AmB was used as a control. The viability of amastigotes was assessed through the parasite rescue and transformation assay, a method described by [Jain et al. \(2012\)](#). Briefly, THP-1 cells were prepared in RPMI-1640 medium containing 10 ng/mL of PMA and dispensed into 96-well culture plates. After 24 h of cell differentiation, THP-1 derived-macrophages were infected with promastigotes at a parasite/macrophage ratio of 10:1. Then, infected macrophages were treated with 8HQN (0.156–20 µg/mL) and AmB (0.004–0.5 µg/mL) prepared in RPMI-1640 medium supplemented with 2% FBS and 25 µg/mL gentamicin sulfate and incubated at 37 °C, 5% CO₂. After exposure to the compound and drug for 48 h, survived amastigotes in macrophages were assessed by means of parasite rescue and formation assay.

Leishmania-infected macrophages were washed with serum-free RPMI-1640 medium. Then, 0.05% (w/v) of sodium dodecyl sulfate (SDS) prepared in RPMI-1640 medium (20 µL/well) was added and incubated for 30 s to lyse the macrophage cell membrane and release intracellular amastigotes. Then, SIM supplemented with 20% FBS, 25 µg/mL gentamicin sulfate (180 µL/well) was added into each well to neutralize the SDS. The culture was incubated at 26 °C for 96 h to allow the amastigotes to grow, transform into promastigotes and start proliferation. Then, parasite proliferation was assessed using alamarBlue cell viability assay. The culture was added with alamarBlue reagent (20 µL/well) and incubated at 26 °C for another 24 h. Then, the absorbance was measured at wavelengths of 570 and 600 nm using an Eon™ microplate spectrophotometer. Wells with non-infected macrophage treated with 0.05% SDS (30 s) and medium containing 20 µL of alamarBlue reagent were included as controls. Dose-response curves were generated using GraphPad Prism software. The IC₅₀ value was determined and expressed as mean ± SD. Results are from three independent experiments.

Drug combination assay and analysis of interaction

Drug interaction was investigated by using the method as previously described by [Intakhan et al. \(2020\)](#). Double concentration of IC₅₀ of 8HQN and AmB were prepared and serially diluted twice in 2%FBS RPMI-1640 medium. Different dilutions of 8HQN and AmB were combined using checker board assay ([Zhao, Kelnar & Bader, 2014](#)). The matrix of 8HQN/AmB provided 12 different combinations. *Leishmania*-infected macrophages were prepared in 96-well culture plates as describe above and treated with all combinations at 37 °C, 5%CO₂ for 48 h. After exposure to combinations, macrophages surviving amastigotes were assessed using parasite rescue and transformation assay as described above. Promastigote proliferation in the culture at 96 h of culture was determined using alamarBlue cell viability assay. Each well was added with 20 µL of alamarBlue reagent

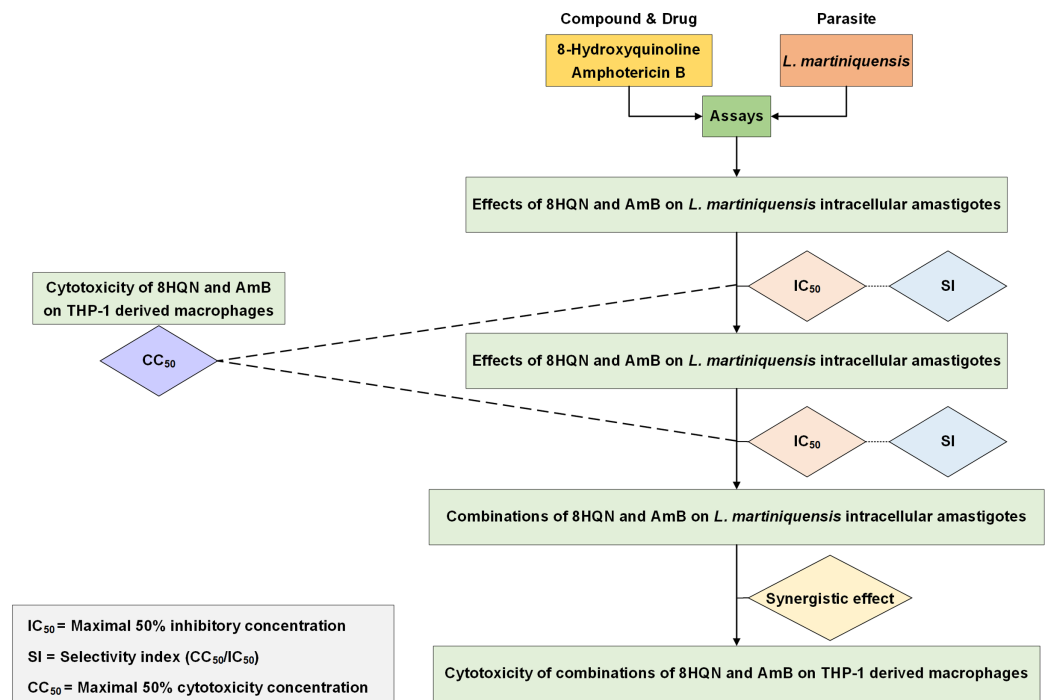

Figure 1 Overall study for 8HQN and AmB treatment in *L. martiniquensis*. The diagram shows processes for determining activity of 8HQN and AmB against promastigotes, intracellular amastigotes and THP-1 cells and processes for investigation of drug interaction and cytotoxicity of combinations.

Full-size DOI: 10.7717/peerj.12813/fig-1

and incubated for 24 h. Controls were wells with non-infected macrophages treated with 0.05% SDS (30 s) and medium containing 10 μ L of alamarBlue reagent. Then, the absorbance was measured at wavelengths of 570 and 600 nm using an EonTM microplate spectrophotometer (BioTek, Winooski, VT, USA). %Growth inhibition was used in the analysis of drug interaction. The interaction of 8HQN and AmB was analyzed using the Chou-Talalay combination index method by using CompuSyn software (Chou, 2008). Then, combinations were classified as synergism, additive or antagonism. Overall study is shown in Fig. 1.

Statistical analysis

All data were recorded, edited and entered using GraphPad Prism software (GraphPad Prism Software, Inc., San Diego, CA, USA). Mean and standard deviation was calculated from three independent experiments. The statistical differences of %growth inhibition between drug combination and 8HQN alone was evaluated using one-way analysis of variance (ANOVA), followed by Dunnett's multiple comparison tests using GraphPad Prism software (GraphPad Prism Software, Inc., San Diego, CA, USA). The statistical differences of cytotoxicity of drug combinations and drug or compound alone were evaluated using ANOVA, followed by Bonferroni's multiple comparison tests. Differences were considered significant when p values were < 0.05 .

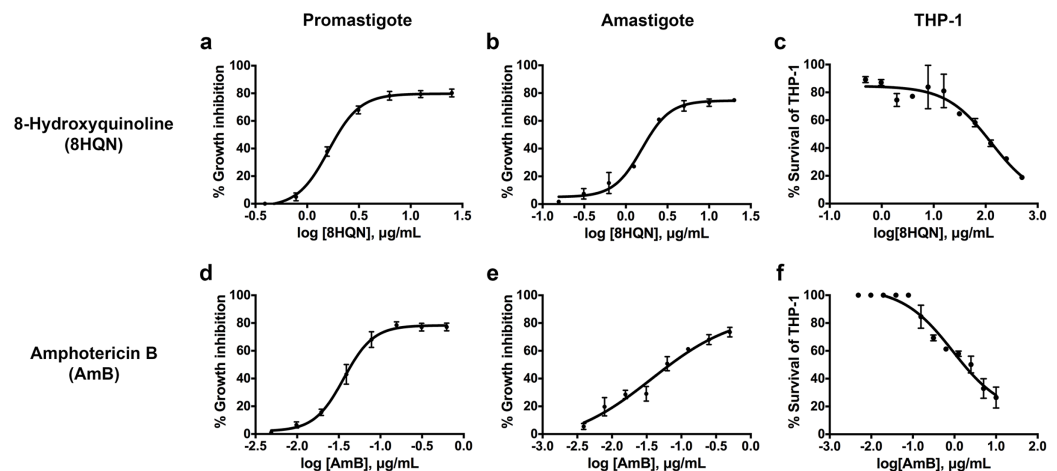

Figure 2 Dose response curves of 8HQN and AmB on *L. martiniquensis* and THP-1 cells. Parasites and THP-1 cells were treated with 8HQN and AmB. Percentages of parasite growth inhibition and THP-1 cell viability were determined using alamarBlue assay. Non-linear regression trendlines obtained by a serial compound or drug dilution were generated by using GraphPad Prism software. (A–C) Dose response curves of 8HQN for promastigotes, amastigotes and THP-1 cells, respectively. (D–F) Dose response curves of AmB for promastigotes, amastigotes and THP-1 cells, respectively.

RESULTS

Effect of 8HQN against *L. martiniquensis* promastigote and intracellular amastigote

8HQN has effect on both the promastigote and intracellular amastigote stages of *L. martiniquensis*. After 8HQN or AmB treatment, parasite growth was determined by the alamarBlue assay. The percentage of growth inhibition was plotted as a function of compound or drug concentration by fitting the values to a non-linear regression analysis. The dose response curves of 8HQN or AmB for promastigotes and amastigotes were generated by GraphPad Prism as shown in Fig. 2. These dose-response curves agree with the law of mass action and inhibition followed a sigmoidal curve. The IC_{50} value of 8HQN for promastigotes was $1.61 \pm 0.28 \mu\text{g/mL}$ (Table 1). Intracellular amastigotes were more sensitive to 8HQN than promastigotes with IC_{50} value of $1.56 \pm 0.02 \mu\text{g/mL}$. The drug AmB showed IC_{50} value of $0.04 \pm 0.02 \mu\text{g/mL}$ and $0.04 \pm 0.01 \mu\text{g/mL}$ for promastigotes and amastigotes, respectively.

Cytotoxicity and selectivity index of 8HQN

The cytotoxicity of 8HQN was evaluated in THP-1 cells. The CC_{50} value of 8HQN was $128.55 \pm 0.92 \mu\text{g/mL}$, showing that it was less toxic to THP-1 cells than the drug, as shown in Table 1. The CC_{50} value of AmB was $0.95 \pm 0.32 \mu\text{g/mL}$. To compare the selectivity index (SI) of 8HQN and AmB, the SI value was calculated from the CC_{50} value divided by IC_{50} value. The SI values of 8HQN obtained from promastigotes and intracellular amastigotes were 79.84 and 82.40, respectively. The SI value of AmB was 23.75 for both promastigotes and intracellular amastigotes. These results showed that 8HQN was more effective in inhibiting parasite growth and safer to host cells than the drug.

Table 1 Anti-*Leishmania* activity, cytotoxicity, and selectivity index of 8HQN and AmB. Growth of parasites and viability of THP-1 cells were determined using alamarBlue assay. The results were expressed as mean \pm SD. The selectivity index (SI) was calculated by the ratio between the CC_{50} and IC_{50} values, respectively.

Biological activity			
Compound ($\mu\text{g/mL}$)	Promastigotes	Amastigotes	THP-1 cells
	IC_{50}^a / SI^d	IC_{50}^b / SI^d	CC_{50}^c
8HQN	$1.61 \pm 0.28/79.84$	$1.56 \pm 0.02/82.40$	128.55 ± 0.92
AmB	$0.04 \pm 0.02/23.75$	$0.04 \pm 0.01/23.75$	0.95 ± 0.32

Synergistic effects of 8HQN in combination with AmB on *L. martiniquensis* amastigote in THP-1 cells

The investigation of the synergistic effect of 8HQN in combination with AmB was performed using the Chou-Talalay combination index method. The IC_{50} values of 8HQN and AmB were $1.47 \pm 0.02 \mu\text{g/mL}$ and $0.09 \pm 0.02 \mu\text{g/mL}$, respectively, which were similar to the previous IC_{50} results. The different concentrations of the combination were obtained from the checkerboard method. After treatment with each combination, the percentage of parasite growth inhibition was calculated from the percentage of treated parasites compared to untreated parasites (control) and then determined the CI value to classify the type of interaction, such as very strong synergism, strong synergism, synergism, moderate synergism, slight synergism, nearly additive, slight antagonism, moderate antagonism, antagonism, strong antagonism, or very strong antagonism. Results showed that the interaction between 8HQN and AmB was found from strong antagonism, nearly additive, to strong synergism as shown in Table 2. Two combinations of 8HQN/AmB (1.6:0.05 and 1.6:0.025 $\mu\text{g/mL}$) were classified as strong synergism. Combination of 1.6 $\mu\text{g/mL}$ of 8HQN plus 0.0125 or 0.00625 $\mu\text{g/mL}$ of AmB were classified as synergism and moderate synergism, respectively. Result showed nearly additive obtained from two combinations of 8HQN/AmB (0.8:0.05 and 0.8:0.025 $\mu\text{g/mL}$). The synergistic and additive effects of the combinations are presented as shown in the isobologram (Fig. 3). The result showed that four data points were below the line of additivity, indicating the synergy of 8HQN and AmB as shown in Fig. 3A. Some combinations indicated additive and antagonistic effects, showing data points near or above the line of additivity, as shown in Fig. 3B. A combination of 8HQN/AmB (1.6:0.00625 $\mu\text{g/mL}$) had the highest dose reduction index (DRI) values in the reduction of AmB used with DRI value of 22.7 (Table 2).

Cytotoxicity of 8HQN/AmB combinations to THP-1 derived macrophages

Four combinations (1.6 $\mu\text{g/mL}$ 8HQN plus 0.05, 0.025, 0.0125 or 0.00625 $\mu\text{g/mL}$ AmB) that provided synergistic effects (Table 2) were tested for their cytotoxicity to THP-1

Table 2 Combinations of 8HQN and AmB on the intracellular amastigotes of *L. martiniquensis* in THP-1 cells.

1.6	0.05	97.00 \pm 3.60****	0.24	Strong synergism	6.07	12.07

Note:

8HQN and AmB were combined at a non-constant ratio. Dose dependent effects were analyzed by CompuSyn software. CI value of each combination was classified as very strong synergism (CI < 0.1), strong synergism (CI = 0.1–0.3), synergism (CI = 0.3–0.7), moderate synergism (CI = 0.7–0.85), slight synergism (CI = 0.85–0.90), nearly additive (CI = 0.90–1.10), slight antagonism (CI = 1.10–1.20), moderate antagonism (CI = 1.20–1.45), antagonism (CI = 1.45–3.30), strong antagonism (CI = 3.30–10), very strong antagonism (CI > 10). DRI is the fold dose of dose reduction allowed in a combination for a given degree of effect as compared with the dose of each 8HQN or AmB alone. Statistical differences between the effects of AmB alone and in combination with 8HQN are indicated as follows: * $p \leq 0.05$; ** $p \leq 0.01$; *** $p \leq 0.001$; **** $p \leq 0.0001$.

Figure 3 Representative normalized isobolograms of interaction between 8HQN and AmB against intracellular amastigote stage of *L. martiniquensis*. (A) 1.6 $\mu\text{g/mL}$ 8HQN plus 0.05, 0.025, 0.0125 or 0.00625 $\mu\text{g/mL}$ AmB. (B) 0.8 $\mu\text{g/mL}$ 8HQN plus 0.05 or 0.025 $\mu\text{g/mL}$ AmB. Data points (dots) located on, below, or above the line indicate additivity, synergy or antagonism, respectively.

Figure 4 Cytotoxic activity of 8HQN in combination with AmB on THP-1 cells. The x axis represents different concentration ($\mu\text{g}/\text{mL}$) of 8HQN plus AmB. Solid bar, untreated control; Green bars, THP-1 cells treated with 1.6 $\mu\text{g}/\text{mL}$ 8HQN plus 0.05, 0.025, 0.0125 or 0.00625 $\mu\text{g}/\text{mL}$ AmB; white bars, THP-1 cells treated with 8HQN (128 $\mu\text{g}/\text{mL}$) or AmB (1 $\mu\text{g}/\text{mL}$). Statistical differences between the effects of 8HQN or AmB at CC_{50} values and their combinations (8HQN plus AmB) or untreated control are indicated as follows: NS, non-significance; ****, $p \leq 0.0001$. [Full-size !\[\]\(1663bb69f307a960345edb0e712f8c02_img.jpg\) DOI: 10.7717/peerj.12813/fig-4](https://doi.org/10.7717/peerj.12813/fig-4)

derived macrophages. 8HQN and AmB, which were prepared at the concentration of CC_{50} , were used as controls. The concentration of combinations providing synergistic effects against parasites showed no toxic effects for host cells, whereas both 8HQN and AmB at the CC_{50} concentration showed about 50% of the host cell viability, as shown in Fig. 4.

DISCUSSION

L. martiniquensis is a member of the subgenus *Leishmania* (*Mundinia*) and is one of the etiological agents of disseminated cutaneous and visceral leishmaniasis in humans (Chusri et al., 2012; Leelayoova et al., 2017; Espinosa et al., 2018; Burza, Croft & Boelaert, 2018; Valero & Uriarte, 2020). AmB is an available drug used for chemotherapy of *L. martiniquensis* infection (Leelayoova et al., 2017). It has proven to be effective against *L. martiniquensis* in vitro (Intakhan et al., 2020). However, the use of this drug is associated with highly toxic side effects (Grela et al., 2018). Thus, to improve the treatment and reduce the side effects of using monotherapy, the search for a new drug or a new natural compound in combination therapy that is less toxic and highly effective has been required.

In this study, the anti-*Leishmania* activity of 8HQN against *L. martiniquensis* was determined both in promastigote and intracellular amastigote stages of parasites, followed by the investigation of drug interaction between 8HQN and AmB. Previously, 8HQN has been shown to inhibit the multiplication of *L. tropica*, *L. major* and *L. infantum* at micromolar concentrations (Dardari et al., 2004). In the present study, *L. martiniquensis* was treated with 8HQN for the first time. 8HQN was able to inhibit the multiplication of promastigotes of *L. martiniquensis* in a microconcentration range. This confirms the

efficacy of 8HQN, although this *Leishmania* species is in a distinct subgenus, *Leishmania* (*Mundinia*). The compound was also able to reach and inhibit the growth of intracellular amastigotes of *L. martiniquensis* within THP-1 derived macrophages, showing the ability to cross the host cell membrane and treat *Leishmania*-infected host cells. Interestingly, 8HQN had low toxicity to THP-1 derived macrophages, similar to a previous study in murine macrophages (Costa Duarte et al., 2016). Upon drug discovery, the compound with anti-*Leishmania* activity is expected to have less toxicity to host cells, showing an SI value higher than 10 (Don & Ioset, 2014).

Our results showed that 8HQN had SI values of 79.84 and 82.40 for promastigote and intracellular amastigote of *L. martiniquensis*, respectively. These SI values were higher than 10 and higher than the SI value of AmB, which highlight promising results for the use of 8HQN in the treatment of *Leishmania*-infected host cells. The mode of action of 8HQN is different, depending on the organism in which the compound acts. In *Schizosaccharomyces pombe* and *Clostridium difficile*, 8HQN acts as a chelating agent, which was able to inhibit RNA synthesis (Fraser & Creanor, 1974; Novakova et al., 2014). In intracellular microbes such as *Cryptococcus neoformans* and *Mycobacterium tuberculosis*, 8HQN activated the Cu-independent antibacterial host responses to kill intracellular pathogens (Festa et al., 2014; Shah et al., 2016). In the present study, a decrease in the number of intracellular amastigotes of *L. martiniquensis* in macrophages after treatment with 8HQN was similar to the results of a previous study in *L. braziliensis*, *L. amazonensis* and *L. infantum* (Costa Duarte et al., 2016). The compound failed to stimulate the production of nitric oxide by macrophages, showing that 8HQN did not activate the host response to kill parasites. However, some anti-*Leishmania* compounds showed the ability to kill parasites by up-regulating the level of ROS, causing oxidative stress (Mesquita et al., 2013). Costa Duarte et al. (2016) proved that 8HQN was unable to induce oxidative stress, but acted directly on parasite mitochondria, affecting the parasite mitochondrial membrane potential, causing parasite death. In addition, 8HQN did not affect the plasma membrane permeability of parasites, which is in contrast to the mechanism of AmB that acts on parasite plasma membrane by binding to ergosterols to form pores, resulting in parasite cell lysis (Mishra, Saxena & Singh, 2007). Furthermore, 8HQN alone and in a form of compound-containing polymeric micelle system have been proved to be effective against *L. amazonensis*-chronically infected BALB/c mice, suggesting the use of this compound *in vivo* (Costa Duarte et al., 2016; Lage et al., 2016).

In an attempt to reduce the side effects of AmB in monotherapy, 8HQN was combined with the drug and tested in intracellular amastigotes of *L. martiniquensis* to investigate its efficacy. Our results showed that 8HQN/AmB combinations provided synergistic effects without cytotoxicity to host cells. The combination between 8HQN 1.6 µg/mL and AmB 0.00625 µg/mL provided the highest DRI, showing approximately a 22-fold reduction in AmB used in the combination.

To date, there are no reports of synergistic effects of 8HQN in combination with AmB on any other species of *Leishmania*. Based on our finding, the synergistic effect of 8HQN with AmB on intracellular amastigotes of *L. martiniquensis*, can be explained by the

ability of AmB to form pores in the parasite membrane, as well as potential direct effects of 8HQN on mitochondrial function.

Drug combinations were recommended to reduce the treatment duration and toxicity and delay the emergence of resistance (*van Griensven et al., 2010*). However, *Leishmania* parasites could develop resistance to drug combinations, leading to the potential risk of resistance to the different drugs used in combinations (*García-Hernández et al., 2012*). Thus, synergistic effects of 8HQN/AmB combinations found in this study can also be considered as an alternative combination therapy for leishmaniasis treatment.

CONCLUSIONS

In conclusion, 8HQN and its combination with AmB were tested on *L. martiniquensis* *in vitro* for the first time. 8HQN was effective against *L. martiniquensis* and worked synergistically with AmB to reduce AmB used in the combination against parasites. These findings suggest that 8HQN can be considered as an alternative treatment for *L. martiniquensis* infection. The use of combinations may also bring significant advantages and better therapeutic effects than AmB alone.

ACKNOWLEDGEMENTS

We thank Assoc. Prof. Dr. Narissara Jariyapan from Chulalongkorn University, Thailand for providing parasites.

ADDITIONAL INFORMATION AND DECLARATIONS

Funding

This work was supported by the Personal Research Grant, Walailak University, Thailand (Grant number WU-IRG-63-078). The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Grant Disclosures

The following grant information was disclosed by the authors:
Walailak University, Thailand: WU-IRG-63-078.

Competing Interests

The authors declare that they have no competing interests.

Author Contributions

- Wetpisit Chanmol performed the experiments, analyzed the data, prepared figures and/or tables, authored or reviewed drafts of the paper, and approved the final draft.
- Padet Siriyasatien analyzed the data, authored or reviewed drafts of the paper, and approved the final draft.
- Nuchpicha Intakhan conceived and designed the experiments, performed the experiments, prepared figures and/or tables, authored or reviewed drafts of the paper, and approved the final draft.

Data Availability

The following information was supplied regarding data availability:

The raw measurements are available in the [Supplementary Files](#).

Supplemental Information

Supplemental information for this article can be found online at <http://dx.doi.org/10.7717/peerj.12813#supplemental-information>.
