Research Paper

The prevalence of common mental disorders among healthcare professionals during the COVID-19 pandemic at a tertiary Hospital in Addis Ababa, Ethiopia

ARTICLE INFO ABSTRACT Keywords: Background: Coronavirus disease 2019 (COVID-19) has resulted in unprecedented morbidity, mortality, and Addis Ababa health system crisis leading to a significant psychological destress on healthcare workers (HCWs). The study COVID-19 aimed to determine the prevalence of symptoms of common mental disorders among HCWs during the COVID-19 Ethiopia pandemic at St. Paul's Hospital, Ethiopia. Health professional Methods: A self-administered cross-sectional study was conducted to collect socio-demographic information and Mental disorder symptoms of mental disorders using validated measurement tools. Accordingly, PHQ-9, GAD-7, ISI, and IES-R Prevalence were used to assess the presence of symptoms of depression, anxiety, insomnia, and distress, respectively. Chisquare test, non-parametric, and logistic regression analysis were used to detect risk factors for common mental disorders. Results: A total of 420 healthcare workers participated in the survey. The prevalence of symptoms of depression, anxiety, insomnia, and psychological distress was 20.2%, 21.9%, 12.4%, and 15.5% respectively. Frontline HCWs had higher scores of mental health symptoms than non-frontline healthcare workers. Binary logistic regression analysis showed that being married was associated with a high level of depression. Furthermore, working in a frontline position was an independent risk factor associated with a high-level of symptoms of depression, anxiety, and psychological distress. Limitations: It is a single-center cross-sectional study and the findings may not be nationally representative or reveal causality. Conclusions: A significant proportion of healthcare workers are suffering from symptoms of mental disorders. Frontline HCWs were at a greater risk of severe symptoms. Therefore, psychological interventions should be implemented to support health professionals, especially frontline workers.

1. Introduction

Coronavirus disease 2019 (COVID-19) is a mild to severe respiratory illness that is caused by a coronavirus named severe acute respiratory syndrome coronavirus 2 (SARS COV2). It was first recognized in China in late December 2019 as an unknown respiratory disease outbreak. Due to its high risk of contiguity and human-to-human transmission, it has reached a global pandemic level in a very short period of time (Guan et al., 2020; Lai et al., 2020a).

Healthcare workers (HCWs) dealing with COVID-19 are under increased psychological pressure, and experience high rates of psychiatric morbidity, resembling the situation during the previous severe acute respiratory syndrome (SARS) and influenza epidemics (Bohlken et al., 2020; Li et al., 2020). Depression, anxiety, insomnia, and psychological distress are the common mental health disorders that occur during such a dramatic global health crisis (Liu et al., 2020; Pappa et al., 2020). A study among 1257 healthcare professionals in a tertiary hospital in China, revealed a high prevalence of mental health symptoms

Received 20 May 2021; Received in revised form 19 September 2021; Accepted 1 October 2021 Available online 8 October 2021 2666-9153/© 2021 The Author(s). Published by Elsevier B.V. This is an open access article under the CC BY-NC-ND license (http://creativecommons.org/licenses/by-nc-nd/4.0/).

among HCWs during the early period of the pandemic. Overall, 50.4%, 44.6%, 34.0%, and 71.5% of health workers reported symptoms of depression, anxiety, insomnia, and distress, respectively. Nurses, females, and frontline HCWs were affected more than others with these mental disorders (Lai et al., 2020b). Likewise, the prevalence of symptoms of depression, anxiety, insomnia and distress was observed in 77.6%, 60.2%, 50.4%, and 76.4% respectively among healthcare workers in Turkey (Sahin et al., 2020). More recently, symptoms of depression and anxiety were reported in 15.7% and 41.2% frontline healthcare workers respectively in Bangladish (Tasnim et al., 2021). In a systematic review of 74 studies from 10 areas in Asia, Europe, North America and South America, the pooled prevalence of depression, anxiety, mental distress, and post-traumatic stress symptoms was 23.9%, 23.2%, 11.6%, and 28% respectively among health professionals during the COVID-19 epidemic (Zhao et al., 2021). In a recent study from Ethiopia, anxiety was observed among 26.8% of health professionals during the early period of COVID-19 pandemic (Dagne et al., 2021). In another study, psychological distress was reported in 40.2% of HCWs in South West Ethiopia (Hajure et al., 2021).

To date, studies on the psychological impact of COVID-19 among HCWs in Ethiopia are limited. Therefore, the present study tries to fill the gap of information and identifies the prevalence of depression, anxiety, insomnia, and psychological distress and associated factors among HCWs in Ethiopia.

2. Methods and materials

2.1. Participants

The study was conducted at St. Paul's Tertiary Hospital, the secondlargest public hospital in Addis Ababa, Ethiopia. A total of 2308 frontline and non-frontline HCWs were involved in clinical care of patients suffering from COVID-19 in the hospital during the month of August 2020. Here, frontline HCWs are those participants who were directly engaged in clinical activities of diagnosing, treating, or providing nursing care to patients with confirmed COVID-19. Non-frontline HCWs are those participants who were not directly engaged in clinical activities of diagnosing, treating, or providing nursing care to patients with confirmed COVID-19 but could be indirectly exposed while involved in the care of other patients who might be in a pre-symptomatic stage of COVID-19.

A cross-sectional survey was conducted to assess the prevalence of depression, anxiety, insomnia, and mental distress among the HCWs at St. Paul's Hospital from August 1st, 2020 up to August 30, 2020. Sample size was calculated based on a single population formula for a finite population of 2308 HCWs with a 95% confidence interval, 5% margin of error, and taking the highest of the prevalence's of depression, anxiety, insomnia, and distress of 71.5% from similar studies (C. Lai et al., 2020; Zhu et al., 2020). By considering a 10% non-response rate and applying a sample correction formula, the total sample size was 272 HCWs. However, to allow for subgroup analysis, we amplified the sample size by 50% to reach 430 HCWs. HCWs 18 years or older and currently involved in patient care were included in the study. Those with previous mental illnesses or did not give consent were excluded from the study.

2.2. Procedure

Participants were recruited using a simple random sampling method from their alphabetical list prepared by the human resource development directorate after first stratifying them into four groups (doctors, nurses/ midwives, laboratory professionals, and pharmacy professionals) using probability proportional to size method. Three-fourth of the sample size was recruited from the COVID-19 treatment unit where participants were directly involved with the care of COVID-19 patients (frontline). The rest was from other units where participants might be exposed indirectly (non-frontline).

2.3. Measures

Data were collected using a self-administered questionnaire to assess for symptoms of depression, anxiety, insomnia, and distress using validated measurement tools in the country's official language (Amharic).

Patient Health Questionnaire-9 (PHQ-9) is a nine-item self-report scale designed to screen for depression. It examines how frequently participants were bothered by problems in the previous two weeks. Items are rated on a 4-point Likert-type scale, ranging from 0 (not at all) to 3 (nearly every day). The total scores range from 0 to 27, and was interpreted as: normal (0–4), mild (5–9), moderate (10–14), and severe (15–21) depression. The cut-off score for diagnosis of depression was 10 (Gelaye et al., 2014; Hanlon et al., 2015; Johnson et al., 2019). In the present study, the overall Cronbach's alpha of the PHQ-9 for depression subscale was 0.86, indicating good internal consistency.

General Anxiety Disorder-7 (GAD-7) is a seven-item self-report questionnaire designed to screen for anxiety. GAD-7 examines how frequently participants have been disturbed by problems in the preceding two weeks. Items are rated on a 4-point Likert-type scale, ranging from 0 (not at all) to 3 (nearly every day). Total scores range from 0 to 21. It was used to assess the severity of symptoms of anxiety, and was interpreted as: normal (0–4), mild (5–9), moderate (10–14), and severe (15–21) anxiety. The cut-off score for diagnosis of anxiety was 9 (Ong, and Suh, 2013; Manzar et al., 2021). In this study, the overall Cronbach's alpha of the GAD-7 questionnaire was 0.88, showing good reliability.

The Insomnia Severity Index (ISI) is a seven-item self-report questionnaire evaluating the nature, severity, and impact of insomnia. The ISI assesses participants' difficulty in falling asleep, difficulty in remaining asleep, very early waking, the satisfaction derived from the sleep pattern, impairments emerging in day to day functioning, awareness of sleep-related impairments, and stress levels caused by sleep problems in the previous two weeks. Items are rated on a 5-point Likerttype scale, ranging from 0 (no problem) to 4 (very severe problem). Total scores range from 0 to 28, and was interpreted as: normal (0–7), sub-threshold (8–14), moderate (15–21), and severe (22–28) insomnia. The cut-off score for diagnosis of insomnia was 15 (Ong, J. C., and Suh, 2013; Johnson et al., 2019; Manzar et al., 2020). In our study, the overall Cronbach's alpha of the ISI questionnaire for insomnia subscale was 0.81, indicating good internal consistency.

The Impact of Event Scale-Revised (IES-R) is a 22-item self-report questionnaire evaluating psychological distress. The IES-R investigates how frequently participants have been troubled by problems in the previous two weeks. Items are rated on a 5-point Likert-type scale, ranging from 0 (not at all) to 4 (extremely). Total scores range from 0 to 88, and was interpreted as: normal (0–8), mild (9–25), moderate (26–43), and severe (44–88) distress. A cut-off score for diagnosis of distress was 33 (Creamer et al., 2003). In the present study, the overall Cronbach's alpha of the IES-R for distress subscale was 0.83, indicating good reliability.

Demographic data were self-reported by the participants, including educational level (graduate, post-graduate), profession (doctor, nurse/ midwife, laboratory professional or pharmacy professional), sex (male or female), age (18–25, 26–30, 31–40, or >40 years), marital status, monthly net salary, work experience (<5, 5-10, or >10 years), and technical title (junior or senior). The different technical titles of respondents refer to the professional titles certificated by the Ethiopian Food, Medicine and Health Care Administration, and Control Authority (EFMHACA). Participants were asked whether they were directly engaged in clinical activities of diagnosing, treating, or providing nursing care to patients with confirmed COVID-19. Those who responded yes were defined as frontline workers, and those who answered no were defined as non-frontline workers.

2.4. Statistical analysis

Data were first entered and cleaned using EPI data version 7 and then exported into SPSS version 23 for statistical analysis. All categorical variables were presented as numbers and percentages. The original scores of the 4 measurement tools were continuous, not normally distributed, and thus presented as a median and interquartile range (IQR). A nonparametric Mann-Whitney U test and Kruskal-Wallis H test were applied to compare the severity of each symptom between two or more groups. The ranked data, which were derived from the counts of each level for symptoms of depression, anxiety, insomnia, and distress, were presented as numbers and percentages. To determine for factors associated with symptoms of depression, anxiety, insomnia, and distress, first a univariate analysis was performed for all variables and those with p < 0.2 on univariate analysis were entered into a multivariable logistic regression analysis. The associations between risk factors and outcomes were presented as odds ratios (ORs) and 95% CIs, after adjustment for confounders, including age, sex, marital status, profession, educational level, technical rank, monthly salary, work experience, and working position (frontline or non-frontline). Hosmer-Lemeshow was used for the evaluation of the calibration of the regression model. Finally, a pvalue <0.05 in the multivariable model was considered as significant.

2.5. Ethical approval

This study was approved by the Institutional Review Board of St. Paul's Hospital Millennium Medical College (Reference No. PM 23/10). Written informed consent was obtained from all participants. Each staff's information was collected by residents and nurses using an anonymous pre-coded structured questionnaire that was assigned to each selected HCW. The code was blinded to both data collectors and data entry clerks. The information was kept confidential among the investigators. A staff that had severe symptoms of mental disorder was traced by a psychiatrist (one of the investigators) and advised on further evaluation and treatment. Those who volunteered were linked to our psychiatric clinic.

Table 1

Socio-demographic characteristics of participants, St. Paul's Hospital, 2020.

3. Results

3.1. Socio-demographic characteristics of study participants

A total of 420 participants completed the questionnaire making a response rate of 97.7%. Of these, 115 (27.4%) participants were doctors, 237 (56.4%) were nurses and midwives, 40 (9.5%) were laboratory professionals and 28 (6.7%) were pharmacy professionals. The response rates for doctors, nurses or midwives, laboratory professionals, and pharmacy professionals were 92%, 100%, 100%, and 100% respectively. The mean age of the participants was 28±5.4 [range: 20-57] years. Among the participants, 212 (50.5%) were in the age range of 26-30 years. Two-hundred-forty-six (58.6%) participants were men and 296 (70.5%) were unmarried. The qualification of participants indicated that 295 (70.2%) had undergraduate level and 125 (29.8%) had a postgraduate level of education. Regarding their technical title, 237 (56.4%) were junior and 183 (43.6%) were senior staffs in their professional career. The mean monthly salary of respondents was 167 ± 84.7 United States Dollar (USD) and 213 (50.7%) respondents earn between 111 and 222 USD. The majority (70.5%) of respondents had a work experience of fewer than five years and 296 (70.5%) were frontline healthcare professionals. A significant proportion of respondents working as frontline were aged between 26 and 30 years, unmarried, and nurses or midwives. They had an undergraduate level of education and work experience of fewer than five years (Table 1).

3.2. The prevalence of symptoms of mental disorders

The prevalence of symptoms of the mental disorders was computed from the pre-specified cut-off values of PHQ-9 score \geq 10 for depression, GAD-7 score \geq 9 for anxiety, ISI score \geq 15 for insomnia, and IES-R score \geq 33 for psychological distress diagnosis. Based on the above cut-off scores, the prevalence of depression, anxiety, insomnia, and psychological distress was found to be 20.2%, 21.9%, 12.4%, and 15.5% respectively. The median (IQR) scores on the PHQ-9, GAD-7, ISI, and IES-R for all respondents were 4.0(1.0–9.0), 3.0(0–8.0), 4.0(1.0–9.0), and 11.0(4.0–25.0), respectively. Symptoms of depression, anxiety,

Abbreviations: GAD-7, 7-item Generalized Anxiety Disorder; IES-R, 22-item Impact of Event Scale–Revised; ISI, 7-item Insomnia Severity Index; PHQ-9, 9item Patient Health Questionnaire

insomnia, and distress were reported in higher proportion of frontline healthcare workers (i.e. depression among frontline vs non-frontline: 70 [23.6%] vs 15 [17.6%]; P<0.001; anxiety among frontline vs non-frontline: 75[25.3%] vs 17 [13.7%]; P = 0.003; insomnia among frontline vs non-frontline: 43[14.5%] vs 9 [7.3%]; P = 0.003; and distress among frontline vs non-frontline: 60 [20.3%] vs 5 [4.0%]; P < 0.001) (Table 2).

3.3. Severity of symptoms of mental disorders and associated factors

Moderate symptoms of depression, anxiety insomnia, and distress was reported in 57(13.6%), 49(11.7%), 43(10.2%), and 71(16.9%) respondents respectively. Severe symptoms of depression, anxiety insomnia, and distress was also reported in 28(6.7%), 24(5.7%), 9 (2.1%), and 30(7.1%) respondents respectively. The proportion of frontline HCWs who experienced moderate to severe symptoms of anxiety, insomnia, and distress was greater than non-frontline HCWs (Table 3).

3.4. Perception of threat of COVID-19 and effects of psychological protective measures

The following five common risk factors of perception of threat of COVID-19 were assessed: (i) feel of exposure to COVID-19; (ii) resigning

thoughts; (iii) worry of life-threatening situation; (iv) feel of family members and friends' avoidance; and (v) feel of infection of self or family members by COVID-19. Feel of exposure to COVID-19 was reported in 53 (62.4%), 49 (53.3%), 35 (67.3%), and 48 (73.8%) HCWs with symptoms of depression, anxiety, insomnia, and psychological distress respectively. Thought of resigning from work due to COVID-19 was reported in significantly higher proportion of respondents with symptoms of depression, anxiety, insomnia, and psychological distress (p-values: 0.005, 0.007, <0.001, and <0.001 respectively) (Table 4).

The study also assessed whether or not the respondents were satisfied with the psychological protective measures implemented at St. Paul's Hospital. The common protective measures assessed were as follows: (i) care provided by hospital administrators; (ii) work-shift arrangement; (iii) coverage of the department with personal protective equipment; and (iv) logistic and accommodation support. Sixty-three (74.1%) respondents with symptoms of depression were not satisfied with the care provided by the hospital administrator. Similarly, 66 (71.7%), 35 (67.3), and 48 (73.8%) HCWs who showed symptoms of anxiety, insomnia, and psychological distress respectively were not satisfied with the care provided by the hospital administrator. Respondents who were satisfied with the work-shift arrangement suffered less from insomnia and psychological distress than those who were not satisfied with this protective measure (p-values: 0.004 and 0.008 respectively) (Table 5).

3.5. Factors associated with symptoms of mental health disorders

A binary logistic regression analysis was conducted to determine the demographic and relevant contextual factors that were associated with mental health illnesses. In the adjusted logistic regression analysis, several factors were independently associated with depression (PHQ-9 score \geq 10), anxiety (GAD-7 score \geq 9), insomnia (ISI score \geq 15), and psychological distress (IES-R score \geq 33). Factors that were independently associated with a higher risk of depression included being married (OR, 2.5; 95% CI, 1.4–4.6; p = 0.03) and working in frontline position (OR, 2.4; 95% CI, 1.2–4.5; p = 0.009). Working in frontline position is also associated with more severe symptoms of anxiety (OR, 2.1; 95% CI, 1.1–3.9; p = 0.02) and psychological distress (OR, 5.9; 95% CI, 2.2–15.5; p < 0.001). (Table 6).

4. Discussion

Our study revealed a high prevalence of mental health symptoms among HCWs at St. Paul's Hospital, with close to one-fifth of respondents screened positive on at least one of the four established measuring tools. The prevalence of depression, anxiety, insomnia, and psychological distress in the study among health professionals was 20.2%, 21.9%, 12.4%, and 15.5% respectively. We also found out that the proportion of frontline HCWs experiencing these adverse mental outcomes was significantly higher than that of non-frontline. Finally, we discovered that being married, having undergraduate level of education, and earning monthly salary below 222 USD were associated with development of severe symptoms of mental health disorders. As a result,

Table 4

Perception of threat of the COVID-19 in binary logistic regression analysis among HCWs dealing with the COVID-19 at St. Paul's Hospital, 2020.

Variable	Diagnosis	5	OR (95% CI)	P value	
		Depression (%)	Non-depression		
		(N=85)	(N=335)		
Feel of exposure to COVID-19	Yes	53 (62.4)	199 (59.4)	1.2 (0.7-2.1)	0.44
*	No	32 (37.6)	136 (40.6)	Ref.	
Thought of resigning from work due to COVID-19	Yes	29 (34.1)	51 (15.2)	2.3 (1.3-4.0)	0.005
	No	56 (65.9)	284 (84.8)	Ref.	
Worried about a life-threatening situation once infected	Yes	54 (63.5)	143 (42.7)	1.8 (1.0-3.0)	0.03
	No	31(36.5)	192 (57.3)	Ref.	
Feel of family members or friends avoidance	Yes	67 (78.8)	216 (64.5)	0.7 (0.4-1.2)	0.20

our findings raise a concern about the psychological well-being of HCWs involved in the care and treatment of COVID-19.

The findings of our survey is consistent with several other studies (Huang and Zhao, 2020; Que et al., 2020; Zhu et al., 2020) conducted during the COVID-19 pandemic. A report by Zhu et al. among 5062 HCWs in China found a significant percentage of mental health symptoms; 13.5% for depression, 24.1% for anxiety, and 29.8% for distress among healthcare workers. Another study by Que et al. from China among 2285 HCWs also identified moderate to severe symptoms of depression, anxiety, and insomnia in 12.8%, 11.6%, and 6.8% of respondents respectively. Similarly, in a recent meta-analysis of thirteen studies, the pooled prevalence of depression was 22.8% and that of anxiety was 23.2% among the HCWs involved in COVID-19 care (Pappa et al., 2020). In the contrary, a report by Lai et al. from China reported depression, anxiety, insomnia, and psychological distress among 50.4%, 44.6%, 34%, and 71.5% of HCWs respectively. This discrepancy is probably due to the differences in the methodology, where by Lai et al. used lower threshold values (scores) for the diagnosis of symptoms of depression, anxiety, insomnia, and distress that might have overrated the prevalence. Had Lai et al. utilized a similar cut-off values to our current study, the prevalence of depression, anxiety, insomnia, and distress would have been 14.8%, 12.3%, 7.7%, and 35% respectively. Therefore, the use of different measuring tools and methodologies, and the use of different classifications even if the same scale was used, leads to very different results being reported for the prevalence of mental disorders (Pappa et al., 2020).

The current study revealed that working in a frontline position was independently associated with higher adverse mental health outcomes, compared to working in a non-frontline environment. Our finding is in line with other recent studies (Alkhamees et al., 2020; Huang and Zhao, 2020; Lai et al., 2020; Que et al., 2020; Zhu et al., 2020), which also reported a significantly higher proportion of severe symptoms of mental disorders among frontline than non-frontline HCWs. Some of the reasons could be; frontline HCWs encounter and witness the suffering of seriously ill and dying-alone patients. They might also be under enormous workload abiding with the strict protective measures, which could make them uncomfortable (Cai et al., 2020; Xiang et al., 2020). However, we did not observe a significantly higher rate of seeking help or receiving treatment for mental problems among these subjects. The phenomenon that HCWs have difficulty accepting and disclosing mental health issues is not unique to the COVID-19 outbreak (Tysser et al., 2004; Fridner et al., 2012). Several studies reported high prevalence of psychological

H.A. Mulatu et al.

Table 5

Psychological protective measures in binary logistic regression analysis among HCWs dealing with the COVID-19 at St. Paul's Hospital, 2020.

distress among HCWs (Cai et al., 2020; Lai et al., 2020; Que et al., 2020; Şahin et al., 2020). However, many of whom do not seek psychological support from their colleagues, because they either think they did not need or are embarrassed to seek help and worried about confidentiality (Fridner et al., 2012; Greenberg et al., 2020). These findings remind that psychologists or psychotherapists should pay more attention to HCWs with mental health problems.

In our study, thought of resigning from work due to COVID-19 was

Table 6

associated with higher risk of severe symptoms of depression, anxiety, insomnia, and distress. On the other hand, being satisfied with the workshift arrangements and logistic support implemented by the hospital administration were the protective factors associated with lower risk of severe symptoms of insomnia and psychological distress. A similar finding was reported from a study conducted during the earlier stage of COVID-19 pandemic in China (Zhu et al., 2020).

Similar to a study from China (Zhu et al., 2020), our finding further indicated that HCWs who were married reported more severe symptoms of depression. This might be due to increased occupational exhaustion and family responsibilities among married than unmarried HCWs. Furthermore, depression was observed in HCWs who have undergraduate as compared with post-graduate level of education. Similar findings were reported by Zhang et al. and Lai et al. This might be attributed to excessive workloads, frequent night shifts, and frequent contact with patients by the undergraduate HCWs who were predominantly nurses and general practitioners than HCWs with postgraduate qualification who were specialist doctors. High levels of anxiety and insomnia were reported in HCWs earning a monthly income of less than 222 USD. This might be due to the fact that a low income is known to be associated with more frequent mental health problems. People of the low income are estimated to be two to three times more likely to have a mental disorder than are those with the highest income (Fang et al., 2021; Kim and Cho, 2020).

The strength of the study was the use of random sampling method with adequate number of participants. However, our study has several limitations which should be addressed in future studies. First, it was a single-center study and the findings may not be nationally representative. Second, it was a cross-sectional study and was not the best method of determining correlation and causation of factors to mental disorders. Third, all the data collected were self-reported by the respondents and could be exposed to social desirability bias. Therefore, a multi-centric and longitudinal study is warranted to address these issues.

5. Conclusion and recommendation

In conclusion, the study demonstrates that a significant proportion of healthcare workers are suffering from symptoms of mental health disorders during the COVID-19 pandemic at St. Paul's Hospital. Being married, low monthly income, undergraduate level of education, and working at frontline position were independently associated with a greater risk of experiencing severe symptoms of mental disorders.

Strategies to provide psychological support to HCWs should be implemented by the hospital administration for the mental health of HCWs in order to control the impact of the Pandemic. Long-term surveillance should be implemented to monitor the mental health of HCWs during the COVID-19 pandemic.

Funding

The work was funded by St. Paul's Hospital Millennium Medical College Research Directorate under a protocol number; PM 23/10. The funder had no role in the design, data collection, analysis, interpretation, and in writing the manuscript.

Authors' contributions

HAM and MT conceived and developed the study protocol and drafted the manuscript. All authors involved in data collection. Interpretation and final review were done by HAM, MT, EW, and TB. All authors approved the final manuscript.

Declaration of Competing Interest

None.

Acknowledgments

We would like to thank St. Paul's Hospital Millennium Medical College Research Directorate for funding the study. We would like to thank all healthcare workers who, despite the increased workload during the COVID-19 crisis, have dedicated their time to answer the survey.
