A R T I C L E I N F O

A B S T R A C T

Brief overview: Current evidence suggests vitamin D replacement may reduce risk for acute respiratory tract infections (ARTI) in people with deficiency or insufficiency, although the effects of supplementation on incidence and severity of ARTI in the general population remain unknown. Oral vitamin D supplemzentation taken at routine doses appears to be generally safe and well tolerated.

Verdict: Current experimental evidence remains inconclusive regarding the effects of vitamin D supplementation in the general population for the prevention and treatment of acute respiratory tract infections (ARTI). There is also insufficient evidence to draw conclusions regarding the impact of vitamin D supplementation on the severity or duration of ARTI, nor on outcomes related to lung injury or hospitalization from ARTI. Based on this rapid review, sources of significant heterogeneity in published clinical trials include: differences study populations, inconsistent assessment of serum status at baseline, dosing variability, varying routes of administration, and/or inconsistent definitions of outcome measures. Experimental evidence and observations in large cohorts are generally consistent that vitamin D deficiency (<50 nmol/L [<20 ng/mL]) and insufficiency (<75 nmol/L [<30 ng/mL]) of serum 25-hydroxycholecalciferol (25-OHD) concentration is associated with increased risk of ARTI, and supplementation for those with deficiency/insufficiency may lead to clinically meaningful reductions in the incidence of ARTI. In this rapid review, vitamin D was primarily administered as oral supplementation, and findings suggested significant differences in daily oral dosing compared to periodic bolus dosing. Based on the available experimental evidence, vitamin D supplementation appears to have a high margin of safety with very few adverse events reported in children or adults from a variety of dosing strategies. Future clinical trials on vitamin D should consider the sources of heterogeneity in the existing experimental research and design trials that account for baseline status, evaluate the potential for prevention and treatment in at risk populations, standardize dosing strategies, assess product quality, assess outcomes according to gold standard definitions/diagnostic methods, and delineate viral ARTI from other causes when possible. The available mechanistic evidence related to immunological requirements for adequate vitamin D, the availability of observational and experimental evidence suggestive of clinically meaningful benefits (especially in deficient/insufficient participants), and the high margin of safety, should make vitamin D a high priority for additional clinical research during the current COVID-19 pandemic.

1. Background

Vitamin D, is a fat-soluble, secosteroidal hormone available to humans in the diet, nutritional supplements, and via direct production in the skin upon exposure to adequate ultraviolet light.

Dietary forms of vitamin D include cholecaliferol (vitamin D3) and ergocalciferol (vitamin D2). Vitamin D is most commonly measured in serum as 25-OHD (calcidiol), as reported in this review, and less frequently as the more metabolically active form of 1,25-dihydroxycalcidiol (calcitriol). Vitamin D has numerous fundamental functions in the innate and acquired immune response. Activation of both T- and B- cells leads to upregulation of the vitamin D receptor (VDR), allowing for changes in expression of over 500 vitamin D related genes [1–3]. Select mechanistic effects of Vitamin D on immune function include: enhancement of chemotaxis and phagocytosis [4], regulation of antibody production in B cells [5], inhibition of interleukin (IL)-2, interferon (IFN)-gamma, tumor necrosis factor (TNF)-alpha IL-9, and IL-22 [6–10], and increased IL-3, IL-4, IL-5, and IL-10 [11]. Observational research in the British Birth cohort has demonstrated significant linear relationships between serum 25-OHD concentration and lower risk of acute respiratory tract infection (ARTI), with each 10 nmol/L increase associated with a 7 % lower risk [12]. Further observational research in the United States (US)-based National Health and Nutrition Examination Survey (NHANES) 2001–20016 suggested those with insufficient serum status (25-OHD < 75 nmol/L) had 58% higher adjusted odds of ARTI [13]. Based on the numerous roles of vitamin D in the regulation of immune function, and notable observational research suggesting potential effects on ARTI, numerous randomized controlled trials in adults and children have aimed to learn the direct effects of vitamin D on risk of ARTI and their potential complications. The purpose of this rapid review is to summarize available systematic reviews of randomized, controlled clinical trials of vitamin D on ARTI and related outcomes.

2. Search strategy

2.1. Research question

What are the effects of Vitamin D on acute respiratory tract infections (ARTI) and associated complications?

2.2. Inclusion/exclusion criteria

Reviews were included if they were described as "systematic" and exhibited methods consistent with systematic reviews (i.e., defined clinical question, detailed search protocol, etc.) and reported on human prospective intervention trials sampling adults and/or children with reported ARTI. Reviews were excluded if they were designed as narrative reviews, non-review manuscripts, included only observational studies, and/or the study sample was not reported as diagnosed with ARTI.

2.3. Databases

Medline (OVID), Embase (OVID), AMED (OVID), and CINAHL

2.4. Search terms (example)

Five search strategies were pursued and compiled as follows:
#1: exp Coronavirus Infections/ or exp Coronavirus/ or exp Coronaviridae/ or Influenza, Human/ or Influenza A Virus, H1N1 Subtype/ or Influenza A virus/ or Influenza A Virus, H3N2 Subtype/ or Middle East Respiratory Syndrome Coronavirus/ or respiratory tract infections/ or bronchitis/ or common cold/ or Pneumonia, Viral/ or (Coronavir* or nCov or Influenza or H1N1 or MERS-COV or flu or Bronchit* or cough or rhinosinusit* or rhinit* or common cold or (respiratory adj2 (infect* or illness or symptom* or acute or virus* or disease))).ti,ab,kw.

#2: exp Vitamin D/ or exp Calcitriol/ or exp Cholecalciferol/ or exp Ergocalciferol/ or exp 25-hydroxyvitamin d 2/ or ("Vitamin d$" or "Vit d" or Calcitriol$ or Cholecalciferol or Ergocalciferol or "25-Hydroxyvitamin D 2″).ti,ab,kw

#3: Systematic Review/ or Meta-analysis/ or Systematic Review as Topic/ or Meta-Analysis as Topic/ or Review Literature as Topic/ or (Systematic review or meta analy$ or metaanaly$).ti,ab,kw

#4: comment/ or letter/ or editorial/

#5: (#1 AND #2 AND #3) NOT #4

2.5. Screening

Titles and abstract screening and full text screening were completed by one reviewer and checked for accuracy by a second reviewer. Similarly, data extraction was completed by a single reviewer and checked for accuracy by a second reviewer. Any discrepancies were resolved by consensus.

2.6. Critical appraisal

The critical appraisal tool for this rapid review was performed using the BMJ Best practice criteria for appraising systematic reviews (https://bestpractice.bmj.com/info/toolkit/learn-ebm/appraising-systematic-reviews/) (Table 2).

3. Results

The initial search resulted in 270 citations [Medline (n = 57), Embase (n = 154), AMED (n = 1), and CINAHL (n = 58)], after duplicates (n = 68) were removed, 202 remained for title and abstract screening. Based on title and abstract review, an additional 138 manuscripts were excluded as irrelevant due methodology (i.e., editorials, commentaries, and/or non-systematic reviews), or broad outcome measures (i.e., not focused on ARTI outcomes). Following abstract review, 36 manuscripts were excluded by full text screening due to methodological limitations not apparent in the abstracts (i.e., narrative reviews), leaving 28 manuscripts for detailed extraction. During detailed data extraction, 5 additional manuscripts were excluded due to inclusion of only observational studies, plus 3 additional exclusions included: an editorial (n = 1), a poster citation (n = 1), and a duplicate republished as a report (n- = 1), leaving 20 for the final detailed extraction; see Fig. 1. All citations were imported into Covidence software (Melbourne, Australia) for title and abstract reviews. Full texts were also imported into Covidence for review and data extraction upon finalization of the manuscripts meeting inclusion criteria.

3.1. Critical appraisal

From the appraisal, seven of the 20 reviews met all the requirements. The majority of the studies met most of the criteria in the appraisal tool, however, three reviews were determined to be very poor quality because they met four or fewer of the requirements. The quality of data from these reviews [14–16] in our conclusions and summaries.

3.2. Description of included studies

See Table 1 for a summary of all included studies in the final, detailed review. Of the 20 studies, 13 were systematic reviews and/or of meta-analysis [16–27], 3 were systematic reviews of randomised controlled trials (RCTs) [28–30], 2 were systematic reviews of various studies [14,31] and 1 was a detailed narrative review of RCTs (and therefore was included), despite low formal quality of design [15]. The 2 systematic reviews with various studies included RCTs, cohort studies, case-control series,
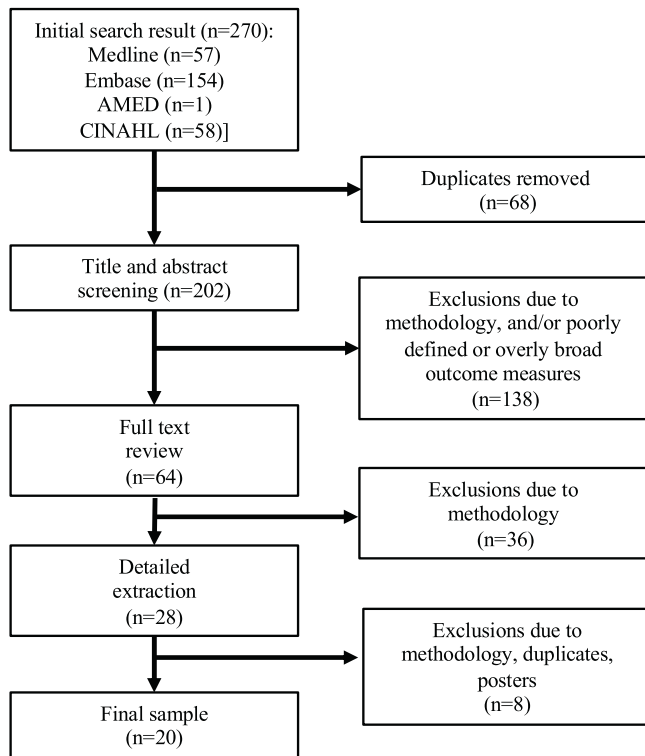

Fig. 1. Search and review flowchart.

retrospective case studies and cross-sectional studies [14,31]. The majority of reviews searched 3 or more databases with Pubmed, Embase, Cochrane, Cinahl and Medline being the main ones [15,17–23,25–32]. Two studies only used one database, Pubmed [14,33] and 1 didn't specify the databases searched [16].

The study population and size, type of respiratory condition, form and dose, and administration route or screening of vitamin D varied across the studies reviewed. Fourteen studies included all populations including children, adults and elderly [14–18,20,22,23,26–30,32] and 5 reviews were conducted on children only [19,21,24,31], 1 was for pregnant women and children [25] and 1 for children and young men [33]. The number of studies included for the reviews on children included 26 in total, encompassing 12 RCTs, 3 cohort, 2 cross-sectional and 9 case-control studies [19,21,24,31]. The pregnancy and children review contained 22 studies including 4 RCTs and 18 observational [25] while the children and young men review contained 10 RCTs [33]. For the studies that included all populations, 222 studies were identified in the reviews. These included 171 RCTs, 24 cohort studies, 8 case-control studies and 4 cross-sectional [14–18,20,22,23,26–30,32].

The 7 reviews which mainly focused on children comprised a total sample of 33,503 participants; of those reviews reporting group allocation, there were 6,474 participants in intervention arms and 6,464 participants in placebo arms [19,21,24,25,31,33]. The fourteen studies that included all population groups comprised a total sample of 314,979 participants; of those reviews reporting group allocation, there were 41,738 participants in intervention arms and 39,655 participants in placebo arms. [14–18,20,22,23,26–30,32].

Sixteen reviews addressed oral administration of vitamin D [15–17,19–27,30,31,33], 2 reviews addressed intravenous and oral administration of vitamin D [29,32] and 3 reviews did not state the route of administration (and focused solely on serum concentrations of vitamin D) [14,18,28].

The reviews exclusive to children all used oral administration of vitamin D with 4 reviews reporting on administration of a dose ranging from 300 IU -2000 IU per day [19,21,24,31]. In the 2 reviews exclusive to pregnant women plus children and young men plus children, the dose ranged from 800 IU-2000 IU daily [25,33]. The oral doses for vitamin D in the reviews of all ages varied dramatically from 100 IU to 100,000 IU. See Table 3 for dosage range included in each review.

3.3. Summary of findings

The measurement outcomes from the reviews varied; however, the primary outcome measure evaluated for this review was the incidence of ARTIs (n = 13) [14,15,17,18,20–23,25,27–29,31]. The other main outcome measures included were: the association between vitamin D levels and ARTI risk (5 reviews) [16,26,32,33], pneumonia incidence (3 reviews) [14,19,24], and frequency of hospitalization rates (2 reviews) [14,24]. Several individual reviews reported additional, less specific, outcomes including: frequency of doctor visits, [25], asthma exacerbations [25], incidence of influenza [14], tuberculosis [15] and extra-skeletal disease [30].

Of the 21 reviews, 15 concluded vitamin D was safe and has the potential reduce the risk of ARTI [15–18,22,23,25,27,29–33]. The other 6 reviews each concluded that there was insufficient evidence to support the protective effect of vitamin D for ARTIs [14,19–21,24,28].

3.4. Reviews supporting a protective effect of vitamin D and ARTI

Autier P., et al. (2017) concluded vitamin D may help to prevent the common upper respiratory tract infections and asthma exacerbation. A 6% risk reduction with vitamin D3 supplementation was identified for clinical RTIs but was of borderline statistical significant; relative risk (RR) = 0.94 [95 % CI: 0.88, 1.00] [32]. They hypothesized vitamin D supplementation may exert immunomodulating effects leading to reduced risk of ARTI.

Bergman P., et al. (2013) concluded vitamin D has a protective effect against RTI; odds ratio (OR) = 0.64 [95 % CI: 0.49, 0.84]. They also identified that the protective effect was larger in studies that used once-daily dosing compared to bolus doses, OR = 0.51 vs. OR = 0.86 respectively (p < 0.01 for difference) [27].

Charan J., et al. (2012) concluded the overall events of ARI in vitamin D group were 21.7 % (205/943) whereas in placebo group it was 30.1 % (279/925), or an -8.4 % absolute risk reduction in favour of vitamin D. According to their random effects model in children and adults combined, there was significant reduction in the incidence of respiratory tract infection in vitamin D group as compared to placebo group; OR = 0.58 [95 % CI: 0.42, 0.81], p < 0.001. In their random effects model for children only (2 studies), vitamin D supplementation reduced the risk of respiratory tract infections significantly (OR = 0.58 [95 % CI: 0.42, 0.815], p < 0.001), with identical risk reduction in their fixed effects model (OR = 0.58 [95 % CI: 0.42, 0.81], p < 0.001). Limiting analyses to trials in adults only (3 studies), the point estimate for risk favoured vitamin D supplementation but was not statistically significant [22].

Christensen N., et al. (2017) concluded RCTs results and effects from supplementation differed depending on the baseline 25OHD concentration. However, overall the level I-II moderate to high quality evidence suggested vitamin D has a protective effect for RTI's. (dose >800 IU/day) [25].

Jat K.R., et al. (2017) found that children with lower RTI were found to have significantly lower mean vitamin D levels as compared to controls. There was likewise a correlation between vitamin D levels and incidence and severity of RTI's.

Table 1 (Continued)

Author	Year	Design	Types of Studies included	Databases Used	Intervention	Participants	Number of Studies	#RCT	Route of Administration (PO, IV)	Total n	Dose	Placebo or other control	N in intervention and placebo/control	Measure of Outcome	Outcome
															an effective adjuvant in the anti-infective therapy.
Reinehr, T.	2018	MA	MA of RCT	Not reported	Vitamin D, any form	Children, adolescents and adults	Unspecified	MA and RCTs	PO	Unspecified	400-1000 IU	Placebo	Not stated	ARTI, influenza Asthma symptoms	Potentially reduces the risk of influenza in school aged children, and higher dose in children aged 1-5 did not make a difference. Both had lower number of ARI. Improves asthma and hospital admission.

SR = systematic review, MA = meta-analysis, RCT = randomized clinical trial, ARTI = acute respiratory tract infection, LRTI = lower respiratory tract infection, URTI = upper respiratory tract infection, CS = Cohort Studies, CCS = Case Control Studies, RCS = Retrospective Case Studies, CSS = Cross-Sectional Studies.

Jayawardena R., et al. (2020) concluded serum status is likely to be a predictor of immune responses to vitamin D supplementation, and ARTI may be significant lower in vitamin D groups among elderly participants in long term care facilities, but concluded most trials demonstrated no overall differences in the incidence of upper respiratory tract infections between vitamin D and controls, likely due to participant and dosing heterogenicity [29].

Larkin A., et al. (2013) results showed that a vitamin D deficiency was notably prevalent among both mothers and infants and deficiency was associated with an increased risk of ARTIs [31].

Maretzke F., et al. (2020) concluded observational data supported primary prevention, with a significant inverse association between vitamin D status and risk of ARTIs, with RCTs supporting similar conclusions [30].

Martineau A., et al. (2016) found that vitamin D supplementation reduced risk of ARTIs among all participants (adjusted OR = 0.88 [95 % CI: 0.81, 0.96]; p for heterogeneity <0.001). Protective effects seen in those receiving daily or weekly vitamin D without additional bolus doses. Among those receiving daily or weekly vitamin D, protective effects were stronger in those with baseline 25-OHD levels <25 nmol/L (adjusted OR = 0.30 [95% CI: 0.17, 0.53]) compared to those with baseline 25-OHD levels ≥25 nmol/L (adjusted OR = 0.75 [95% CI: 0.60, 0.95]) p for interaction=0.006. Vitamin D did not influence the proportion of participants experiencing at least one serious adverse event (adjusted OR = 0.98 [95% CI: 0.80, 1.20], p = 0.83) [23].

Martineau A., et al. (2017) concluded vitamin D supplementation resulted in statistically significant reduction in the proportion of participants experiencing at least one ARTI. Vitamin D supplementation was a strong protective factor among people with a baseline circulating 25-OHD <25 nmol/L; however, no significant effects among those with levels of ≥25 nmol/L. Baseline vitamin D status and dosing frequency independently modified the effect of Vitamin D supplementation on risk of ARTI. Daily or weekly vitamin D treatment was associated with a greater degree of protection against ARTI among participants with low baseline levels of 25-OHD. Bolus dose of Vitamin D did not appear to offer protection against ARTI. Vitamin D did not influence the risk of serious adverse events or mortality due to any cause [17].

Moroti R., et al. (2012) concluded 25-OHD at least 10 nmol/L higher than the mean concentration offered protection against ARTI, and vitamin D may be an effective adjuvant in the anti-infective therapy [33].

Reinehr T., et al. (2018) concluded vitamin D may potentially reduce the risk of influenza, improve asthma and reduce exacerbation of bronchiole spasms, but had no impact on severity of bronchiole spasms [16].

Rejnmark L., et al. (2017) concluded 3 out of 7 meta-analysis reported beneficial effects of Vitamin D supplementation on RTI while the rest reported null effects. In 2 RCTs, vitamin D supplementation significantly reduced the risk of RTI by 40 % in paediatric population. The risk of ARTI was significantly reduced in 25 RCTs in the general population (OR = 0.88 [95 % CI: 0.81, 0.96]. Response to a daily or weekly vitamin D dose showed as a protective effects, but null effect in response to one or more bolus doses [18].

Zittermann A., et al. (2015) concluded vitamin D deficiency increased the risk of ARTI but there was no evidence vitamin D lowered risk of other common infections. They also recommended supplementation with vitamin D (dose 600-2,000 IU/day) for prophylaxis, particularly in winter, due to the high vitamin D deficiency found in the European population [15].

U/S = unspecified; B = bolus dosing; IV = intravenous administration; X indicates the review identifies the use of this dose in the studies they reviewed.

3.5. Reviews supporting null effects of vitamin D and ARTI

Jolliffe D., et al. (2013) concluded observational studies found a statistical significance between vitamin D deficiency and increased risk of ARTIs. However, they also identified conflicting RCTs, and therefore concluded vitamin D supplementation did not conclusively demonstrate protection against ARTIs [14].

Mao et al. (2013) reported a pooled RR = 0.98 [95% CI: 0.93–1.03], p = 0.45 of ARTI from vitamin D supplementation and, therefore, concluded the routine use of vitamin D supplementation cannot be recommended for ARTI prevention in healthy populations healthy populations [26].

Xiao L, et al. (2015) reported no significant decreases in the incidence of ARTI (RR = 0.79 [95% CI: 0.55, 1.13]), all-cause mortality (RR = 1.18 [95% CI: 0.71–1.94]), or the rate of hospitalization due to RTI's in healthy children (RR = 0.95 [95% CI: 0.72, 1.26]) from vitamin D supplementation [21].

Yakoob M., et al. (2016) concluded, based on moderate quality evidence, there was no effect of vitamin D supplementation on the occurrence of pneumonia; nor any effect in children with

pneumonia. No conclusions could be made regarding whether vitamin D influenced hospital admissions as there was only one small study assessing this outcome, which had very low quality [24]. The types or causes of pneumonia were not specifically evaluated.

Vuichard Gysin et al. (2016) reported a pooled risk of ARTI 6% lower in the vitamin D group compared to non-treatment group, a 10 % lower risk of lab-confirmed ARTI among vitamin D group, a marginal mean reduction in symptom duration, and lower symptom severity in vitamin D groups; however the point estimates for these risk reductions did not reach statistically significance [20].

Yamshchikov A., et al. (2009) reported no difference in frequency, severity, or duration of upper respiratory tract infections (URTIs), but statistical trends favoured vitamin D in all outcomes, including a lower frequency of wintertime URTI symptoms in intervention group, and a lower frequency of reported URTI symptoms while receiving 2,000 IU vitamin D3/ day compared to 800 IU vitamin D3/day. However, the difference in infection rates between groups was no longer significant after 6 months of intervention. There was also no difference in the change in CD4 count or viral load between groups [28].

4. Clinical significance

Despite several positive systematic reviews and meta-analyses, the available experimental evidence related to the effects of vitamin D on acute respiratory tract infection (ARTI) is plagued with heterogeneity and mixed quality, and therefore is insufficient to recommend vitamin D supplementation to the general population as a protective agent against ARTI. However, based on the evidence identified in this rapid review (including a high margin of clinical safety), combined with strong mechanistic rationale, the following recommendations can be made for those at risk of ARTI: 1. vitamin D status should be tested for those at risk of ARTI; 2. patients identified with deficiency or insufficiency should be supplemented with vitamin D until their status is normalized; and 3. daily dosing of vitamin D3 is preferred to achieve serum concentrations >50 nmol/L in a timely manner. Clinical trials support vitamin D doses of 800 IU/day up to 10,000 IU/day [34], with 1,000–2,000 IU/day being a common dosing strategy in clinical trials, and potentially more effective then lower daily or bolus dosing strategies.
