Abstract. Solute carrier (SLC) drug transporters exchange various molecules without energy from adenosine triphosphate hydrolysis, indicating an association with anticancer drug resistance. However, the expression and role of SLC transporters in malignant tumors has not yet been fully elucidated. Therefore, in the current study, the expression of SLC37A family genes was evaluated in patients with colorectal cancer (CRC), and it was revealed that SLC family 37 member 1 (SLC37A1) expression was significantly increased in tumorous tissues compared with that in non-tumorous tissues. The cases with upregulated expression of SLC37A1 by immunohistochemical staining were significantly associated with positive venous invasion and liver metastasis. Furthermore, upregulated SLC37A1 expression was associated with poor overall survival time in the present cohort. These results indicated that SLC37A1 is involved in the hematogenous metastasis of CRC. To investigate whether SLC37A1 is associated with hematogenous metastasis and glycolipid metabolism, SLC37A1 was knocked down in colon cancer cells, and the expression of sialyl Lewis A and sialyl Lewis X was observed to be decreased. In summary, upregulation of SLC37A1 was observed in patients with CRC, and was associated with poor patient outcomes and survival. To the best of our knowledge, the present study is the first to propose a key role of SLC37A1 in CRC, and additional studies are warranted to reveal the functional role of SLC37A1 in CRC development.

Introduction

Colorectal cancer (CRC) is one of the leading causes of cancer-associated mortality in the USA and East Asia (1-3). While segmental surgical resection of the colon or rectum is the standard treatment, surgery alone is not sufficient to cure the majority of patients with CRC (4). Patients who experience local or distant recurrences following surgery require chemotherapy (4). Furthermore, patients with stage III CRC, as well as selected patients with stage II, also require adjuvant chemotherapy to reduce the risk of recurrence (5). 5-Fluorouracil (5-FU) has been used as a standard chemotherapy regimen in the past few decades and remains a key drug in several recently introduced combination chemotherapies (6). FOLFOX [folinic acid (LV), 5-FU and oxaliplatin] and FORFIRI (LV, 5-FU and irinotecan) provide a high response rate, and their therapeutic effect is evident in numerous patients with CRC (7-10). However, drug resistance to these combination chemotherapies has finally occurred and may be a major problem in the treatment of CRC (11).

One of the mechanisms of drug resistance is the transportation of anticancer drugs out of cells, and the major drug transporters are the adenosine triphosphate (ATP)-binding cassette (ABC) and solute carrier (SLC) superfamilies (12). ABC transporters contain membrane proteins that translocate a variety of substrates across extra- and intracellular membranes, and use the energy from ATP binding/hydrolysis to transport multiple types of drugs, including anticancer agents (13). *In vitro* studies have revealed that more than half of ABC transporters are associated with chemotherapy failure (14). The most characterized ABC transporter is ABCB1 (also known as multidrug resistance protein 1), the overexpression of which in tumor cells has been associated with drug resistance to molecularly targeted and chemotherapy drugs (15,16). By contrast, SLC drug transporters do not rely on ATP and uptake small molecules into cells (12). While cancer cells express several different types of ABC transporters to gain drug resistance (17), the expression of SLC transporters in malignant tumors remains unknown. SLC transporters include almost 400 members organized into 52 families, and it has been reported that certain transporters, including SLC22A6 and SLC22A8 from the SLC22 family,

transport methotrexate (18). The present study suggested that SLC transporters may also be associated with drug resistance (18). However, the molecular functions of the majority of SLC transporters in cancer remain to be elucidated.

The SLC37 family consists of four proteins, namely A1, A2, A3 and A4, which are involved in sugar-phosphate exchange (19). SLC37A4 is known as a glucose-6-phosphate (G6P) transporter that performs an important role in glucose production (19); however, the functional role of other SLC37 family genes is not yet fully understood. However, since this transporter functions in glycolipid metabolism, it has been hypothesized that abundant expression of SLC37 family genes is involved in cancer development (19). It is known that oncogenes and tumor-suppressor genes dysregulate glucose transport and energy metabolism pathways due to satisfy the requirement of a large amount of glucose for cancer cells (20,21). Therefore, a previous study investigated the roles of SLC transporters and expected them to be a useful therapeutic target (12).

In the current study, SLC37 family gene expression was investigated in patients with CRC. Furthermore, to clarify the functional role of SLC37 genes, the association between SLC37 gene expression and glycolipid metabolism was investigated.

Materials and methods

Clinical samples of patients. A total of 231 surgical specimens obtained from 231 patients with CRC who had undergone surgical resection at Fukushima Medical University Hospital (Fukushima, Japan) between January 1991 and December 2007 were included in the present study. In 10 cases, messenger RNAs (mRNAs) were extracted from cancer tissues and adjacent non-tumor tissues. Information regarding age, sex, tumor-node-metastasis stage and pathological diagnosis, including lymphatic and venous invasion, was retrospectively collected (Tables III and IV). The carcinomas at the time of primary tumor resection were staged according to the Union for International Cancer Control classification (7th classification) (22,23). Written informed consent was obtained from all patients. The present study was approved by the ethics committee of Fukushima Medical University (approval no. 1476).

Cell line culture. The colon cancer cell lines (SW620, LoVo, SW480, HCT116, SW48, HCT15, RKO, SW837, COLO-201, COLO-205, LS174T and LS180) used in the present study were originally obtained from the American Type Culture Collection (Manassas, VA, USA). The cells were cultured in the recommended media (Dulbecco's modified Eagle's medium (Thermo Fisher Scientific, Inc., Waltham, MA, USA) for RKO, LS174T and LS180 and RPMI-1640 medium (Sigma-Aldrich; Merck KGaA, Darmstadt, Germany) for SW480, Lovo, HCT15, SW48, SW620 and HCT116 supplemented with 10% fetal bovine serum (Thermo Fisher Scientific, Inc.). The monolayer cells were maintained in a 37˚C incubator with 5% CO_2, observed regularly under a light microscope (magnification, x40) and subcultured when they reached 80-90% confluency.

Reverse transcription-quantitative polymerase chain reaction (RT-qPCR). Total RNA was extracted from the tissues and cells using TRIzol reagent (Thermo Fisher Scientific, Inc., Waltham, MA, USA) according to the manufacturer's protocol, as previously described (24). Complementary DNA (cDNA) was synthesized from 5 μg of total RNA with a random hexamer using the SuperScript III First-Strand Synthesis System (Thermo Fisher Scientific, Inc.). The cDNAs from the CRC tissues were used for the measurement of four SLC37 family genes. β-actin was used as an internal control. Primer sequences are shown in Table I. To quantify the gene expression, the band was scanned, and a densitometry analysis was performed using the software ImageJ version 1.51k (National Institutes of Health, Bethesda, MD, USA). The experiment was repeated at least two times.

RT-qPCR amplification of the SLC37A1 gene was performed with the GeneAmp PCR System 9700 (Thermo Fisher Scientific, Inc.) at 94˚C initial denaturation for 5 min, followed by 25-35 cycles of 94˚C for 1 min, 55-60˚C for 45 sec and 72˚C for 45 sec. These cDNAs were used for the measurement of gene expression by real-time PCR with an Applied Biosystems® 7500 Real-time PCR system (Thermo Fisher Scientific, Inc.) using TaqMan® probes that were purchased from Thermo Fisher Scientific, Inc., and β-actin was used as an internal control: SLC37A1 (catalog no., Hs00375251_m1) and β-actin (catalog no., Hs99999903_m1). Relative SLC37A1 gene expression was calculated using the $2^{-\Delta\Delta Cq}$ method (25), according to the supplier's protocol (Thermo Fisher Scientific, Inc.). This sets the average control expression at 1. This experiment was repeated this three times.

Immunohistochemical (IHC) staining and evaluation. IHC staining was carried out on paraffin-embedded histological sections (4-μm thick) using a polymer peroxidase method in which colon cancer specimens were fixed in 20% phosphate-buffered formalin (pH 7.4) at room temperature overnight. Following deparaffinization with xylene and rehydration using alcohol-water mixtures, prior to heat treatment in 10 mM citric acid (pH 6.0) for antigen retrieval, the sections were treated with 0.3% hydrogen peroxide in methanol for 30 min at room temperature to block endogenous peroxidase activity. Subsequent to rinsing in PBS, the sections were incubated with anti-SLC37A1 antibody (catalog no., HPA030418; dilution, 1:200; Atlas Antibodies, Bromma, Sweden) at 4˚C overnight. An additional wash in PBS was followed by treatment with a peroxidase-labeled polymer conjugated to goat anti-rabbit immunoglobulins (Dako EnVision+ System-HRP Labelled Polymer; ready-to-use; catalog no., K4003; Dako; Agilent Technologies, Inc., Santa Clara, CA, USA), as the secondary antibody for 30 min at room temperature. The staining was visualized with 3,3'-diaminobenzidine, followed by counterstaining with hematoxylin.

Expression of SLC37A1 proteins was evaluated using optical microscopy (BX43; Olympus Corporation, Tokyo, Japan) as positive when detected in the nucleus of the tumorous tissue, but not in the nucleoli, cytoplasm or endoplasmic reticulum, and the total field of view was observed at x400 magnification. Blinded to the origin of the features and clinical outcomes, the staining of each specimen was evaluated by two independent researches (D.K. and K.S.). Rates were classified as follows: 0-5%, 0; 6-20%, 1; 21-50%, 2; and 51-100%, 3. Staining intensity was scored as 0 (negative), 1 (weak), 2 (moderate) and 3

Table II. Tumor/non-tumor ratio[a] of SLC37A gene expression.

Gene	Case										Mean
	1	2	3	4	5	6	7	8	9	10	
SLC37A1	1.35	1.43	1.27	0.42	0.84	0.84	2.23	3.98	1.70	0.67	1.48
SLC37A2	0.91	1.79	1.01	0.74	1.24	1.54	1.28	0.65	0.86	1.08	1.11
SLC37A3	1.74	1.11	1.29	1.32	0.87	0.89	0.69	0.93	1.10	1.06	1.10
SLC37A4	0.95	1.56	0.95	1.45	0.67	0.89	1.92	1.01	1.24	1.22	1.19

[a]The tumor/non-tumor ratio was calculated from the quantified data of tumor (tumor/β-actin) and non-tumor (non-tumor/β-actin) expression.

(strong). Positive staining was defined by a score of >2, while negative staining was a score of 0 or 1.

Small interfering RNA (siRNA) transfection. A knock-down experiment was performed using the siRNA method with SLC37A1 Stealth RNAi oligos HSS1227622 (SLC37A1-siRNA1) and HSS182427 (SLC37A1-siRNA2) (Thermo Fisher Scientific, Inc.), and Lipofectamine RNAiMAX (Thermo Fisher Scientific, Inc.) according to the manufacturer's protocol. Stealth RNAi siRNA negative control (NC-siRNA) (catalog no. 12935-300; Thermo Fisher Scientific, Inc.) was used as control. One day prior to transfection, a CRC cell line, LS180, was seeded at 5×10^5 cells per well on a 6-cm plate. Transfection with a final concentration of 40 nM siRNA was conducted when the cell density was 30-50% on the plates, and the plates were then incubated for 48 h at 37˚C.

Fluorescence-activated cell sorting (FACS). FACS was employed to characterize sialyl Lewis A and sialyl Lewis X protein expression levels. The anti-sialyl Lewis A antibody (catalog no., 2D3; Seikagaku Kogyo Co., Ltd., Tokyo, Japan) and anti-sialyl Lewis X (catalog no., 2H5; Seikagaku Kogyo Co., Ltd.) were prepared as previously described (26). For flow-cytometric analysis, the cells were harvested at a semi-confluent stage and stained with a fluorescein isothiocyanate-conjugated secondary antibody for 30 min at 25˚C (diliution, 1:250; Chemicon; EMD Millipore, Billerica, MA, USA) prior to analysis using FACSCanto II (BD Biosciences, San Jose, CA, USA).

Statistical analysis. Statistical analysis was carried out with an unpaired Student's t-test using GraphPad Prism v5.0 (GraphPad Software, Inc., La Jolla, CA, USA). Survival curves were generated by the Kaplan-Meier method and compared by log-rank tests. Univariate and multivariate Cox regression analyses were performed by JMP 10 software (SAS Institute, Inc., Cary, NC, USA). P<0.05 was considered to indicate a statistically significant difference.

Results

Upregulated SLC37A1 expression is associated with worse patient outcomes. To investigate SLC37A family gene expression in CRC, the mRNA expression of each cluster gene was investigated in 10 representative cases using RT-qPCR (Fig. 1A and Table I). While all SLC37A family genes were detected in tumor and adjacent non-cancerous tissue, SLC37A1 expression appeared to be markedly increased in tumor tissue compared with its expression in non-tumor tissue (Table II). To investigate these comparisons, SLC37A1 protein expression was evaluated by IHC staining in 231 patients with CRC (Fig. 1B). SLC37A1 expression was positive in 157 cases (68.0%) and negative in 74 cases (32.0%). SLC37A1 expression was observed in the nucleus of cancer cells of patients with CRC.

SLC37A1 expression level was then compared with clinicopathological factors in patients with CRC (Table III). The SLC37A1 expression level was not associated with age, sex, stage, tumor location, histology, depth of invasion, lymphatic invasion or lymph node metastasis. However, positive expression of SLC37A1 was significantly associated with positive venous invasion (P=0.034) and liver metastasis (P=0.013). Based on the Kaplan-Meier analysis, positive expression of SLC37A1 was significantly associated with worse overall survival (P=0.019) (Fig. 1C). This association was marginally significant (P=0.085) and independent of all clinical covariates

Table III. Clinicopathological factors and SLC37A1 IHC expression.

IHC, immunohistochemistry; SLC37A1, solute carrier family 37 member 1.

in multivariate models (Table IV), demonstrating the potential for SLC37A1 as a useful prognostic biomarker for CRC.

Knockdown of SLC37A1 decreases sialyl Lewis A and X expression in colon cancer cells. To evaluate the role of SLC37A1 in glycolipid metabolism, gene knockdown technology was used to investigate sialyl Lewis A and X expression. SLC37A1

expression in the 12 colon cancer cell lines (SW620, LoVo, SW480, HCT116, SW48, HCT15, RKO, SW837, COLO-201, COLO-205, LS174T and LS180) used in the present study was evaluated in order to select appropriate cells for the experiment (Fig. 2A). SLC37A1 was then knocked down by siRNA oligonucleotide in LS180 cells (SLC37A1-siRNA), which originally expressed upregulated SLC37A1 (Fig. 2B).

Table IV. Univariate and multivariate Cox regression analyses of SLC37A1 expression levels and other clinical covariates.

Clinical covariates	Univariate analysis		Multivariate analysis[a]	
	HR (95% CI)	P-value	HR (95% CI)	P-value
SLC37A1 expression (positive vs. negative)	2.25 (1.04-5.59)	0.04	2.02 (0.91-5.14)	0.09
Age (≥65 years vs. 65< years)	1.18 (0.60-2.36)	0.63		
Sex (male vs. female)	0.89 (0.46-1.77)	0.74		
Location (right vs. left)	0.97 (0.44-1.98)	0.94		
Stage (II-IV vs. 0-I)	8.83 (1.91-157)	0.18×10^{-2}	0.66×10^{10} (1.07-37.0)	0.04
Histology (others vs. well)[b]	3.53 (1.63-8.79)	0.09×10^{-2}	2.90 (1.33-7.26)	0.01
ly (present vs. absent)	3.25 (1.16-13.6)	0.02	1.11 (0.38-4.72)	0.87
v (present vs. absent)	5.16 (1.56-31.8)	0.04×10^{-1}	2.21 (0.64-14.0)	0.24
n (positive vs. negative)	4.47 (2.24-9.51)	$<0.01 \times 10^{-2}$	3.79 (1.81-8.53)	0.03×10^{-2}

[a]Final models included all variables that were moderately associated with survival (P<0.05) in the univariate analysis. [b]Histology was compared between others (moderately- and poorly-differentiated and mucinous) vs. well (well-differentiated). HR, hazard ratio; CI, confidence interval; SLC37A1, solute carrier family 37 member 1; ly, lymphatic invasion; v, venous invasion; n, node stage.

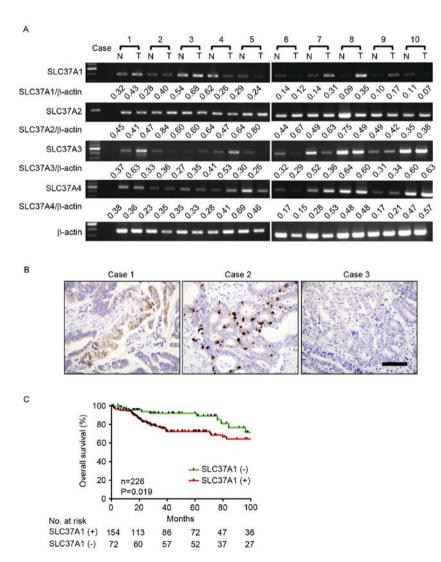

Figure 1. Expression of SLC37 family genes in patients with CRC. (A) Messenger RNA expression of SLC37 genes in patients with CRC. In total, 10 representative cases of tumor and non-tumor cells were analyzed by reverse transcription-quantitative polymerase chain reaction. β-actin was used as a loading control. Gene expression was quantified by the National Institutes of Health software ImageJ version 1.51k. (B) Immunohistochemical staining of SLC37A1 in CRC. Representative image of positive (cases 1 and 2) and negative (case 3) staining are shown. Scale bar, 100 μm. (C) Kaplan-Meier survival of 226 available CRC cases of the present cohort stratified by SLC37A1 tumor expression. CRC, colorectal cancer. T, tumor; N, non-tumor; SLC37A1, solute carrier family 37 member 1.
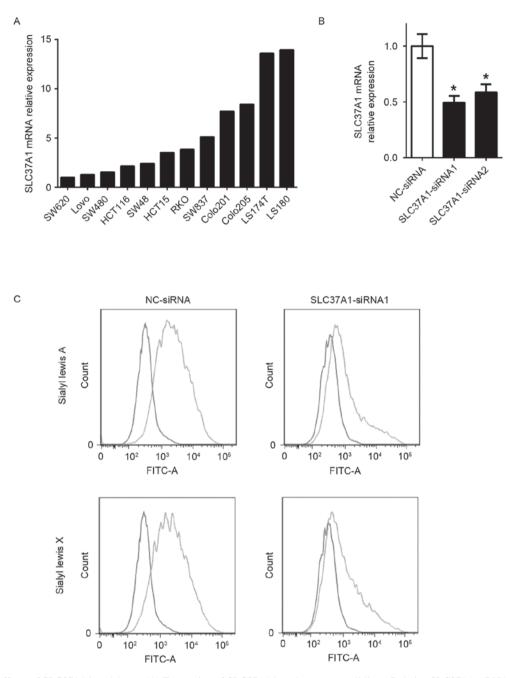

Figure 2. *In vitro* effects of SLC37A1 knockdown. (A) Expression of SLC37A1 in colon cancer cell lines. Relative SLC37A1 mRNA expression levels to SW620 (expression in SW620 cells was considered as 1) are shown (normalized to β-actin). (B) Expression of SLC37A1 in SLC37A1-knockdown LS180 cells (SLC37A1-siRNA1 and SLC37A1-siRNA2) and negative control cells (NC-siRNA). Data are presented as the mean ± standard deviation. *P<0.05. (C) Flow-cytometric analysis of sialyl Lewis A and sialyl Lewis X expression in negative control cells (NC-siRNA; blue line in upper panels) and SLC37A1-knockdown LS180 cells (SLC37A1-siRNA1; blue line in lower panels). The red line represents the staining control (both upper and lower panels). FITC, fluorescein isothiocyanate; siRNA, small interfering RNA; NC, negative control; SLC37A1, solute carrier family 37 member 1.

While no morphological changes were observed in the SLC37A1-knockdown cells, the expression of sialyl Lewis A and sialyl Lewis X was markedly reduced compared with that in NC-siRNA cells (Fig. 2C).

Discussion

In the present study, increased SLC37A1 expression was observed in patients with CRC, which was associated with positive venous invasion and liver metastasis. The present study confirmed that the tumor expression of SLC37A1 is upregulated at the mRNA and protein levels in patients with CRC, whereas other SLC37A family genes are not upregulated. Furthermore, positive expression of SLC37A1 is associated with poor patient survival, indicating an oncogenic role of SLC37A1 in CRC.

SLC37A1, located at chromosome 21q22.3, is one of the SLC37 family genes, and is abundantly expressed in the adult kidney, bone marrow, intestine, spleen and liver (27). While the functional role of SLC37A1 has not yet been characterized, an association with glycolipid metabolism has been suggested (28). SLC37A1 shares 30% of sequence similarity

with the glycerol-3-phophate (G3P) transporter; therefore, SLC37A1 may be a G3P transporter (19,27). By contrast, SLC37A1 also appears to function as a G6P transporter (29), indicating that even its fundamental role as a transporter remains controversial. It has been reported that SLC37A1 appears to be involved in phospholipid biosynthesis, indicating that SLC37A1 may accelerate cell proliferation (30). It appears that cells express SLC37A1 transporters to gain drug resistance, but the cell viability did not significantly differ between LS180 cells with high SLC37A1 expression and SW480 cells with low SLC37A1 expression (data not shown). *In vitro* experiments revealed that the expression of SLC37A1 was upregulated by epidermal growth factor (EGF) via the EGF receptor (EGFR)/mitogen-activated protein kinase/Fos transduction pathway in breast cancer cell lines (30). Since SLC37A1 expression was not associated with EGFR expression by IHC evaluation in the present cohort (data not shown), SLC37A1 may be upregulated by the downstream factor of EGFR signaling. The EGFR signaling pathway is also activated by KRAS mutations in CRC, indicating that SLC37A1 upregulation is involved in CRC tumor development. Approximately 50% of CRC cases have KRAS mutations (31), and they do not respond to anti-EGFR antibody therapy (32). This means that upstream inhibition of EGFR has no therapeutic effect in CRC cases with KRAS mutations (32). In addition, thus far, KRAS mutation has not served as a direct druggable target (33,34). Therefore, to identify a candidate therapeutic target downstream of KRAS is reasonable.

Sialyl Lewis A and sialyl Lewis X are ligands for the adhesion molecule E-selectin, which is expressed in vascular endothelial cells and is associated with tumor metastasis, recurrence and overall survival in various patients with cancer (35). Our previous study reported that sialyl Lewis A and sialyl Lewis X were significantly induced by upregulation of uridine diphosphate-galactose transporter and hypoxia (26,36). These carbohydrate antigens are responsible for the adhesion of cancer cells to the endothelium during metastasis (37). In the present study, positive SLC37A1 expression in CRC tumor tissue was associated with the presence of liver metastasis, indicating that SLC37A1 performs an important role in the hematogenous metastasis of CRC. Therefore, SLC37A1 was knocked down in colon cancer cells, and a significant reduction of sialyl Lewis A and sialyl Lewis X expression was observed. These results indicated that induced SLC37A1 expression in CRC tumor tissue accelerates cancer metastasis and may be a therapeutic target in patients with CRC.

In conclusion, to the best of our knowledge, the present study is the first to report that SLC37A1 is upregulated in CRC and is associated with poor patient outcomes. Additional studies are required to investigate the possibility of SLC37A as a candidate therapeutic target or biomarker to detect high-risk patients.
